## Contents

### 2.8. Statistical values

2.8.1. TIMCUMSUM - Cumulative sum over all timesteps

2.8.2. CONSECSTAT - Consecute timestep periods

2.8.3. VARSSTAT - Statistical values over all variables

2.8.4. ENSSTAT - Statistical values over an ensemble

2.8.5. ENSSTAT2 - Statistical values over an ensemble

2.8.6. ENSVAL - Ensemble validation tools

2.8.7. FLDSTAT - Statistical values over a field

2.8.8. ZONSTAT - Zonal statistical values

2.8.9. MERSTAT - Meridional statistical values

2.8.10. GRIDBOXSTAT - Statistical values over grid boxes

2.8.11. REMAPSTAT - Remaps source points to target cells

2.8.12. VERTSTAT - Vertical statistical values

2.8.13. TIMSELSTAT - Time range statistical values

2.8.14. TIMSELPCTL - Time range percentile values

2.8.15. RUNSTAT - Running statistical values

2.8.16. RUNPCTL - Running percentile values

2.8.17. TIMSTAT - Statistical values over all timesteps

2.8.18. TIMPCTL - Percentile values over all timesteps

2.8.19. HOURSTAT - Hourly statistical values

2.8.20. HOURPCTL - Hourly percentile values

2.8.21. DAYSTAT - Daily statistical values

2.8.22. DAYPCTL - Daily percentile values

2.8.23. MONSTAT - Monthly statistical values

2.8.24. MONPCTL - Monthly percentile values

2.8.25. YEARMONSTAT - Yearly mean from monthly data

2.8.26. YEARSTAT - Yearly statistical values

2.8.27. YEARPCTL - Yearly percentile values

2.8.28. SEASSTAT - Seasonal statistical values

2.8.29. SEASPCTL - Seasonal percentile values

2.8.30. YHOURSTAT - Multi-year hourly statistical values

2.8.31. DHOURSTAT - Multi-day hourly statistical values

2.8.32. YDAYSTAT - Multi-year daily statistical values

2.8.33. YDAYPCTL - Multi-year daily percentile values

2.8.34. YMONSTAT - Multi-year monthly statistical values

2.8.35. YMONPCTL - Multi-year monthly percentile values

2.8.36. YSEASSTAT - Multi-year seasonal statistical values

2.8.37. YSEASPCTL - Multi-year seasonal percentile values

2.8.38. YDRUNSTAT - Multi-day daily running statistical values

2.8.39. YDRUNPCTL - Multi-day daily running percentile values

### 2.9. Correlation and co.

2.9.1. FLDCOR - Correlation in grid space

2.9.2. TIMCOR - Correlation over time

2.9.3. FLDCOVAR - Covariance in grid space

2.9.4. TIMCOVAR - Covariance over time

### 2.10. Regression

2.10.1. REGRES - Regression

2.10.2. DETREND - Detrend time series

2.10.3. TREND - Trend of time series

2.10.4. TRENDARITH - Add or subtract a trend

### 2.11. EOFs

2.11.1. EOF - Empirical Orthogonal Functions

2.11.2. EOFCOEFF - Principal coefficients of EOFs

### 2.12. Interpolation

2.12.1. REMAPBIL - Bilinear interpolation

2.12.2. REMAPBIC - Bicubic interpolation

2.12.3. REMAPNN - Nearest neighbor remapping

2.12.4. REMAPDIS - Distance weighted average remapping

---

2.12.4. REMAPDIS - Distance weighted average remapping

2.12.3. REMAPNN - Nearest neighbor remapping

2.12.2. REMAPBIC - Bicubic interpolation

2.12.1. REMAPBIL - Bilinear interpolation

2.11.2. EOFCOEFF - Principal coefficients of EOFs

2.11.1. EOF - Empirical Orthogonal Functions

2.10.4. TRENDARITH - Add or subtract a trend

2.10.3. TREND - Trend of time series

2.10.2. DETREND - Detrend time series

2.10.1. REGRES - Regression

2.9.4. TIMCOVAR - Covariance over time

2.9.3. FLDCOVAR - Covariance in grid space

2.9.2. TIMCOR - Correlation over time

2.9.1. FLDCOR - Correlation in grid space

2.8.39. YDRUNPCTL - Multi-year daily running percentile values

2.8.38. YDRUNSTAT - Multi-year daily running statistical values

2.8.37. YSEASPCTL - Multi-year seasonal percentile values

2.8.36. YSEASSTAT - Multi-year seasonal statistical values

2.8.35. YMONPCTL - Multi-year monthly percentile values

2.8.34. YMONSTAT - Multi-year monthly statistical values

2.8.33. YDAYPCTL - Multi-year daily percentile values

2.8.32. YDAYSTAT - Multi-year daily statistical values

2.8.31. DHOURSTAT - Multi-day hourly statistical values

2.8.30. YHOURSTAT - Multi-year hourly statistical values

2.8.29. SEASPCTL - Seasonal percentile values

2.8.28. SEASSTAT - Seasonal statistical values

2.8.27. YEARPCTL - Yearly percentile values

2.8.26. YEARSTAT - Yearly statistical values

2.8.25. YEARMONSTAT - Yearly mean from monthly data

2.8.24. MONPCTL - Monthly percentile values

2.8.23. MONSTAT - Monthly statistical values

2.8.22. DAYPCTL - Daily percentile values

2.8.21. DAYSTAT - Daily statistical values

2.8.20. HOURPCTL - Hourly percentile values

2.8.19. HOURSTAT - Hourly statistical values

2.8.18. TIMPCTL - Percentile values over all timesteps

2.8.17. TIMSTAT - Statistical values over all timesteps

2.8.16. RUNPCTL - Running percentile values

2.8.15. RUNSTAT - Running statistical values

2.8.14. TIMSELPCTL - Time range percentile values

2.8.13. TIMSELSTAT - Time range statistical values

2.8.12. REMAPSTAT - Remaps source points to target cells

2.8.11. VERTSTAT - Vertical statistical values

2.8.10. GRIDBOXSTAT - Statistical values over grid boxes

2.8.9. MERSTAT - Meridional statistical values

2.8.8. ZONSTAT - Zonal statistical values

2.8.7. FLDSTAT - Statistical values over a field

2.8.6. ENSVAL - Ensemble validation tools

2.8.5. ENSSTAT2 - Statistical values over an ensemble

2.8.4. ENSSTAT - Statistical values over an ensemble

1. Introduction

The Climate Data Operator (CDO) software is a collection of many operators for standard processing of climate and forecast model data. The operators include simple statistical and arithmetic functions, data selection and subsampling tools, and spatial interpolation. CDO was developed to have the same set of processing functions for GRIB [GRIB] and NetCDF [NetCDF] datasets in one package.

The Climate Data Interface [CDI] is used for the fast and file format independent access to GRIB and NetCDF datasets. The local MPI-MET data formats SERVICE, EXTRA and IEG are also supported.

There are some limitations for GRIB and NetCDF datasets:

- **GRIB** datasets have to be consistent, similar to NetCDF. That means all time steps need to have the same variables, and within a time step each variable may occur only once. Multiple fields in single GRIB2 messages are not supported!

- **NetCDF** datasets are only supported for the classic data model and arrays up to 4 dimensions. These dimensions should only be used by the horizontal and vertical grid and the time. The NetCDF attributes should follow the GDT, COARDS or CF Conventions.

The main CDO features are:

- More than 700 operators available
- Modular design and easily extendable with new operators
- Very simple UNIX command line interface
- A dataset can be processed by several operators, without storing the interim results in files
- Most operators handle datasets with missing values
- Fast processing of large datasets
- Support of many different grid types
- Tested on many UNIX/Linux systems, Cygwin, and MacOS-X

Latest pdf documentation be found [here](https://code.mpimet.mpg.de/projects/cdo/wiki).

1.1. Installation

CDO is supported in different operative systems such as Unix, macOS and Windows. This section describes how to install CDO in those platforms. More examples are found on the main website ([https://code.mpimet.mpg.de/projects/cdo/wiki](https://code.mpimet.mpg.de/projects/cdo/wiki))

1.1.1. Unix

1.1.1.1. Prebuilt CDO packages

Prebuilt CDO versions are available in online Unix repositories, and you can install them by typing on the Unix terminal

    apt-get install cdo

Note that prebuilt libraries do not offer the most recent version, and their version might vary with the Unix system (see table below). It is recommended to build from the source or Conda environment for an updated version or a customised setting.
### Installation

**Unix OS**

<table>
<thead>
<tr>
<th>OS</th>
<th>CDO Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian</td>
<td>11 (Bullseye) 1.9.10-1</td>
</tr>
<tr>
<td></td>
<td>10 (Buster) 1.9.6-1</td>
</tr>
<tr>
<td></td>
<td>Sid          2.0.6-2</td>
</tr>
<tr>
<td>FreeBSD</td>
<td>13           2.0.6</td>
</tr>
<tr>
<td></td>
<td>12           2.0.6</td>
</tr>
<tr>
<td>openSUSE</td>
<td>Leap 15.3    2.0.6</td>
</tr>
<tr>
<td></td>
<td>Tumbleweed   2.0.6-1</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>18.04 LTS 1.9.3</td>
</tr>
<tr>
<td></td>
<td>20.04 LTS 1.9.9</td>
</tr>
<tr>
<td></td>
<td>22.04 LTS 2.0.4-1</td>
</tr>
</tbody>
</table>

#### 1.1.1.2. Building from sources

**CDO** uses the GNU configure and build system for compilation. The only requirement is a working ISO C++17 and C11 compiler.

First go to the [download](https://code.mpimet.mpg.de/projects/cdo) page to get the latest distribution, if you do not have it yet.

To take full advantage of **CDO** features the following additional libraries should be installed:

- **Unidata NetCDF** library ([https://www.unidata.ucar.edu/software/netcdf](https://www.unidata.ucar.edu/software/netcdf)) version 3 or higher. This library is needed to process NetCDF [NetCDF] files with **CDO**.
- **ECMWF ecCodes** library ([https://software.ecmwf.int/wiki/display/ECC/ecCodes+Home](https://software.ecmwf.int/wiki/display/ECC/ecCodes+Home)) version 2.3.0 or higher. This library is needed to process GRIB2 files with **CDO**.
- **HDF5 szip** library ([https://www.hdfgroup.org/doc_resource/SZIP](https://www.hdfgroup.org/doc_resource/SZIP)) version 2.1 or higher. This library is needed to process szip compressed GRIB [GRIB] files with **CDO**.
- **HDF5** library ([https://www.hdfgroup.org](https://www.hdfgroup.org)) version 1.6 or higher. This library is needed to import CM-SAF [CM-SAF] HDF5 files with the **CDO** operator `import_cmsaf`.
- **PROJ** library ([https://proj.org](https://proj.org)) version 5.0 or higher. This library is needed to convert Sinusoidal and Lambert Azimuthal Equal Area coordinates to geographic coordinates, for e.g. remapping.
- **Magics** library ([https://software.ecmwf.int/wiki/display/MAGP/Magics](https://software.ecmwf.int/wiki/display/MAGP/Magics)) version 2.18 or higher. This library is needed to create contour, vector and graph plots with **CDO**.

**CDO** is a multi-threaded application. Therefore all the above libraries should be compiled thread safe. Using non-threadsafe libraries could cause unexpected errors!

#### Compilation

Compilation is done by performing the following steps:

1. Unpack the archive, if you haven’t done that yet:
   ```bash
gunzip cdo-$VERSION.tar.gz  # uncompress the archive
tar xf cdo-$VERSION.tar     # unpack it
cd cdo-$VERSION
```

2. Run the configure script:
   ```bash
./configure
```
   - Optionally with NetCDF [NetCDF] support:
Installation

After the compilation of the source code do a `make install`, possibly as root if the destination permissions require that.

```
make install
```

The binary is installed into the directory `prefix/bin`. `prefix` defaults to `/usr/local` but can be changed with the `--prefix` option of the configure script.

Alternatively, you can also copy the binary from the `src` directory manually to some bin directory in your search path.

### 1.1.3. Conda

Conda is an open-source package manager and environment management system for various languages (Python, R, etc.). Conda is installed via Anaconda or Miniconda. Unlike Anaconda, miniconda is a lightweight conda distribution. They can be downloaded from the main conda Website ([https://conda.io/projects/conda/en/latest/user-guide/install/linux.html](https://conda.io/projects/conda/en/latest/user-guide/install/linux.html)) or on the terminal

```
wget https://repo.anaconda.com/archive/Anaconda3-2021.11-Linux-x86_64.sh
bash Anaconda3-2021.11-Linux-x86_64.sh
source ~/.bashrc
```

and

```
wget https://repo.continuum.io/miniconda/Miniconda3-latest-Linux-x86_64.sh
sh Miniconda3-latest-Linux-x86_64.sh
```

Upon setting your conda environment, you can install **CDO** using conda

```
conda install cdo
conda install python-cdo
```

### 1.1.2. MacOS

Among the MacOS package managers, **CDO** can be installed from Homebrew and Macports. The installation via Homebrew is straight forward process on the terminal

```
brew install cdo
```
Installation

Introduction

Similarly, Macports

```
port install cdo
```

In contrast to Homebrew, Macport allows you to enable GRIB2, szip compression and Magics++ graphic in CDO installation.

```
port install cdo +grib_api +magicspp +szip
```

In addition, you could also set CDO via Conda as Unix. You can follow this tutorial to install anaconda or miniconda in your computer (https://conda.io/projects/conda/en/latest/user-guide/install/macos.html). Then, you can install cdo by

```
conda install -c conda-forge cdo
```

1.1.3. Windows

Currently, CDO is not supported in Windows system and the binary is not available in the windows conda repository. Therefore, CDO needs to be set in a virtual environment. Here, it covers the installation of CDO using Windows Subsystem Linux (WSL) and virtual machines.

1.1.3.1. WSL

WSL emulates Unix in your Windows system. Then, you can install Unix libraries and software such as CDO or the linux conda distribution in your computer. Also, it allows you to directly share your files between your Windows and the WSL environment. However, more complex functions that require a graphic interface are not allowed.

In Windows 10 or newer, WSL can be readily set in your cmd by typing

```
wsl --install
```

This command will install, by default, Ubuntu 20.04 in WSL2. You could also choose a different system from this list.

```
wsl -l -o
```

Then, you can install your WSL environment as

```
wsl --install -d NAME
```

1.1.3.2. Virtual machine

Virtual machines can emulate different operative systems in your computer. Virtual machines are guest computers mounted inside your host computer. You can set a Linux distribution in your Windows device in this particular case. The advantages of Virtual machines to WSL are the graphical interface and the fully operational Linux system. You can follow any tutorial on the internet such as this one

https://ubuntu.com/tutorials/how-to-run-ubuntu-desktop-on-a-virtual-machine-using-virtualbox#1-overview

Finally, you can install CDO following any method listed in the section 1.1.1.
1.2. Usage

This section describes how to use CDO. The syntax is:

\[
\]

1.2.1. Options

All options have to be placed before the first operator. The following options are available for all operators:

- \(-a\) Generate an absolute time axis.
- \(-b <nb>\) Set the number of bits for the output precision. The valid precisions depend on the file format:

<table>
<thead>
<tr>
<th>Format</th>
<th>Nbites</th>
</tr>
</thead>
<tbody>
<tr>
<td>grb1, grb2</td>
<td>P1 - P24</td>
</tr>
<tr>
<td>ncl, nc2, nc4, nc4c, nc5</td>
<td>I8/I16/I32/F32/F64</td>
</tr>
<tr>
<td>nc4, nc4c, nc5</td>
<td>U8/U16/U32</td>
</tr>
<tr>
<td>grb2, srv, ext, ieg</td>
<td>F32/F64</td>
</tr>
</tbody>
</table>

For srv, ext and ieg format the letter L or B can be added to set the byteorder to Little or Big endian.

- \(--cmor\) CMOR conform NetCDF output.
- \(--C, --color\) Colorized output messages.
- \(--double\) Using double precision floats for data in memory.
- \(--eccodes\) Use ecCodes to decode/encode GRIB1 messages.
- \(-f <format>\) Set the output file format. The valid file formats are:

<table>
<thead>
<tr>
<th>File format</th>
<th>&lt;format&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRIB version 1</td>
<td>grb1/grb</td>
</tr>
<tr>
<td>GRIB version 2</td>
<td>grb2</td>
</tr>
<tr>
<td>NetCDF</td>
<td>nc1</td>
</tr>
<tr>
<td>NetCDF version 2 (64-bit offset)</td>
<td>nc2/nc</td>
</tr>
<tr>
<td>NetCDF-4 (HDF5)</td>
<td>nc4</td>
</tr>
<tr>
<td>NetCDF-4 classic</td>
<td>nc4c</td>
</tr>
<tr>
<td>NetCDF version 5 (64-bit data)</td>
<td>nc5</td>
</tr>
<tr>
<td>SERVICE</td>
<td>srv</td>
</tr>
<tr>
<td>EXTRA</td>
<td>ext</td>
</tr>
<tr>
<td>IEG</td>
<td>ieg</td>
</tr>
</tbody>
</table>

GRIB2 is only available if CDO was compiled with ecCodes support and all NetCDF file types are only available if CDO was compiled with NetCDF support!

- \(-g <grid>\) Define the default grid description by name or from file (see chapter 1.3 on page 18).

Available grid names are: \(r<NX>x<NY>, lon=<LON>/lat=<LAT>, F<XXX>, gme<NI>\)

- \(-h, --help\) Help information for the operators.
- \(--no_history\) Do not append to NetCDF history global attribute.
- \(--netcdf_hdr_pad, --hdr_pad, --header_pad <nbr>\) Pad NetCDF output header with \(nbr\) bytes.
- \(-k <chunktype>\) NetCDF4 chunk type: auto, grid or lines.
- \(-L\) Lock I/O (sequential access).
- \(-m <missval>\) Set the missing value of non NetCDF files (default: \(-9e+33\)).
- \(-O\) Overwrite existing output file, if checked.

Existing output file is checked only for: ens<STAT>, merge, mergetime

- \(--operators\) List of all operators.
- \(-P <nthreads>\) Set number of OpenMP threads (Only available if OpenMP support was compiled in).
- \(--pedantic\) Warnings count as errors.
- \(--percentile <method>\) Percentile method: nrank nist rtype8 numpy numpy_lower numpy_higher numpy_nearest
--reduce_dim     Reduce NetCDF dimensions.
-R, --regular    Convert GRIB1 data from global reduced to regular Gaussian grid (only with cgribex lib).
-r               Generate a relative time axis.
-S               Create an extra output stream for the module TIMSTAT. This stream contains
                the number of non missing values for each output period.
-s, --silent     Silent mode.
--single         Using single precision floats for data in memory.
--sortname       Alphanumeric sorting of NetCDF parameter names.
-t <partab>      Set the GRIB1 (cgribex) default parameter table name or file (see chapter 1.6 on page 24).
                Predefined tables are: echam4 echam5 echam6 mpiom1 ecmwf remo
--timestat_date <srcdate>      Target timestamp (temporal statistics): first, middle, midhigh or last source timestep.
-V, --version    Print the version number.
-v, --verbose    Print extra details for some operators.
-w               Disable warning messages.
--worker <num>   Number of worker to decode/decompress GRIB records.
-z jpeg          SZIP compression of GRIB1 records.
                JPEG compression of GRIB2 records.
                Deflate compression of NetCDF4 variables.

1.2.2. Environment variables

There are some environment variables which influence the behavior of CDO. An incomplete list can be
found in Appendix A.

Here is an example to set the environment variable CDO_RESET_HISTORY for different shells:

  Bourne shell (sh):  CDO_RESET_HISTORY=1 ; export CDO_RESET_HISTORY
  Korn shell (ksh):  export CDO_RESET_HISTORY=1
  C shell (csh):     setenv CDO_RESET_HISTORY 1

1.2.3. Operators

There are more than 700 operators available. A detailed description of all operators can be found in the
Reference Manual section.

1.2.4. Parallelized operators

Some of the CDO operators are shared memory parallelized with OpenMP. An OpenMP-enabled C compiler
is needed to use this feature. Users may request a specific number of OpenMP threads nthreads with the
' -P' switch.

Here is an example to distribute the bilinear interpolation on 8 OpenMP threads:

    cdo -P 8 remapbil,targetgrid infile outfile

Many CDO operators are I/O-bound. This means most of the time is spend in reading and writing the
data. Only compute intensive CDO operators are parallelized. An incomplete list of OpenMP parallelized
operators can be found in Appendix B.

1.2.5. Operator parameter

Some operators need one or more parameter. A list of parameter is indicated by the separator ','.

---
• STRING

String parameters require quotes if the string contains blanks or other characters interpreted by the shell. The following command select variables with the name pressure and tsurf:

    cdo selvar,pressure,tsurf infile outfile

• FLOAT

Floating point number in any representation. The following command sets the range between 0 and 273.15 of all fields to missing value:

    cdo setrtomiss,0,273.15 infile outfile

• BOOL

Boolean parameter in the following representation TRUE/FALSE, T/F or 0/1. To disable the weighting by grid cell area in the calculation of a field mean, use:

    cdo fldmean,weights=FALSE infile outfile

• INTEGER

A range of integer parameter can be specified by first/last[/inc]. To select the days 5, 6, 7, 8 and 9 use:

    cdo selday,5/9 infile outfile

The result is the same as:

    cdo selday,5,6,7,8,9 infile outfile

1.2.6. Operator chaining

Operator chaining allows to combine two or more operators on the command line into a single CDO call. This allows the creation of complex operations out of more simple ones: reductions over several dimensions, file merges and all kinds of analysis processes. All operators with a fixed number of input streams and one output stream can pass the result directly to an other operator. For differentiation between files and operators all operators must be written with a prepended "-" when chaining.

    cdo -monmean -add -mulc,2.0 infile1 -daymean infile2 outfile  (CDO example call)

Here monmean will have the output of add while add takes the output of mulc,2.0 and daymean. infile1 and infile2 are inputs for their predecessor. When mixing operators with an arbitrary number of input streams extra care needs to be taken. The following examples illustrates why.

1. cdo info -timavg infile1 infile2
2. cdo info -timavg infile?
3. cdo timavg infile1 tmpfile
   cdo info tmpfile infile2
   rm tmpfile

All three examples produce identical results. The time average will be computed only on the first input file.

Note(1): In section 1.3.2 we introduce argument groups which will make this a lot easier and less error prone.

Note(2): Operator chaining is implemented over POSIX Threads (pthreads). Therefore this CDO feature is not available on operating systems without POSIX Threads support!
1.2.7. Chaining Benefits

Combining operators can have several benefits. The most obvious is a performance increase through reducing disk I/O:

```
cdo sub -dayavg infile2 -timavg infile1 outfile
```

instead of

```
cdo timavg infile1 tmp1
cdo dayavg infile2 tmp2
cdo sub tmp2 tmp1 outfilem tmp1 tmp2
```

Especially with large input files the reading and writing of intermediate files can have a big influence on the overall performance.

A second aspect is the execution of operators: Limited by the algorithms potentially all operators of a chain can run in parallel.

1.3. Advanced Usage

In this section we will introduce advanced features of CDO. These include operator grouping which allows to write more complex CDO calls and the apply keyword which allows to shorten calls that need an operator to be executed on multiple files as well as wildcards which allow to search paths for file signatures. These features have several restrictions and follow rules that depend on the input/output properties. These required properties of operators can be investigated with the following commands which will output a list of operators that have selected properties:

```
cdo --attribs [arbitrary/filesOnly/onlyFirst/noOutput/obase]
```

- **arbitrary** describes all operators where the number of inputs is not defined.
- **filesOnly** are operators that can have other operators as input.
- **onlyFirst** shows which operators can only be at the most left position of the polish notation argument chain.
- **noOutput** are all operators that do not print to any file (e.g info)
- **obase** Here obase describes an operator that does not use the output argument as file but e.g as a file name base (output base). This is almost exclusively used for operators the split input files.

```
cdo -splithour baseName_
could result in: baseName_1 baseName_2 ... baseName_N
```

For checking a single or multiple operator directly the following usage of --attribs can be used:

```
cdo --attribs operatorName
```

1.3.1. Wildcards

Wildcards are a standard feature of command line interpreters (shells) on many operating systems. They are placeholder characters used in file paths that are expanded by the interpreter into file lists. For further information the Advance Bash Scripting Guide is a valuable source of information. Handling of input is a central issue for CDO and in some circumstances it is not enough to use the wildcards from the shell. That’s why CDO can handle them on its own.
Use single quotes if the input stream names matched to a single wildcard expression. In this case CDO will do the pattern matching and the output can be combined with other operators. Here is an example for this feature:

```
cdo timavg -select,name=temperature 'infile?' outfile
```

In earlier versions of CDO this was necessary to have the right files parsed to the right operator. Newer version support this with the argument grouping feature (see 1.3.2). We advice the use of the grouping mechanism instead of the single quoted wildcards since this feature could be deprecated in future versions.

**Note:** Wildcard expansion is not available on operating systems without the `glob()` function!

### 1.3.2. Argument Groups

In section 1.2.6 we described that it is not possible to chain operators with an arbitrary number of inputs. In this section we want to show how this can be achieved through the use of operator grouping with angled brackets `[]`. Using these brackets CDO can assign the inputs to their corresponding operators during the execution of the command line. The ability to write operator combination in a parenthesis-free way is partly given up in favor of allowing operators with arbitrary number of inputs. This allows a much more compact way to handle large number of input files.

The following example shows an example which we will transform from a non-working solution to a working one.

```
cdo -infon -div -fldmean -cat infile1 -mulc,2.0 infile2 -fldmax infile3
```

This example will throw the following error:

```
cdo (Warning): Did you forget to use '[ ' and/or ' ]' for multiple variable input operators?  
cdo (Warning): use option --variableInput, for description  
cdo (Abort): Too few streams specified! Operator div needs 2 input streams and 1 output stream!
```

The error is raised by the operator `div`. This operator needs two input streams and one output stream, but the `cat` operator has claimed all possible streams on its right hand side as input because it accepts an arbitrary number of inputs. Hence it didn’t leave anything for the remaining input or output streams of `div`. For this we can declare a group which will be passed to the operator left of the group.

```
cdo -infon -div -fldmean -cat [ infile1 -mulc,2.0 infile2 ] -fldmax infile3
```

For full flexibility it is possible to have groups inside groups:

```
```
1.3.3. Apply Keyword

When working with medium or large number of similar files there is a common problem of a processing step (often a reduction) which needs to be performed on all of them before a more specific analysis can be applied. Usually this can be done in two ways: One option is to use merge to glue everything together and chain the reduction step after it. The second option is to write a for-loop over all inputs which perform the basic processing on each of the files separately and call merge on the results. Unfortunately both options have side-effects: The first one needs a lot of memory because all files are read in completely and reduced afterwards while the latter one creates a lot of temporary files. Both memory and disk IO can be bottlenecks and should be avoided.

The apply keyword was introduced for that purpose. It can be used as an operator, but it needs at least one operator as a parameter, which is applied in parallel to all related input streams in a parallel way before all streams are passed to operator next in the chain.

The following is an example with three input files:

\[
\text{cdo -merge -apply,-daymean [ file1 file2 file3 ] outfile}
\]

would result in:

\[
\text{cdo -merge -daymean file1 -daymean file2 -daymean file3 outfile}
\]

Figure 1.1.: Usage and result of apply keyword

Apply is especially useful when combined with wildcards. The previous example can be shortened further.

\[
\text{cdo -merge -apply,-daymean [ file? ] outfile}
\]

As shown this feature allows to simplify commands with medium amount of files and to move reductions further back. This can also have a positive impact on the performance.

An example where performance can take a hit.

\[
\text{cdo -yearmean -daymean -merge [ f1 ... f40 ]}
\]

An improved but ugly to write example.

\[
\text{cdo -yearmean -merge [ -daymean f1 -daymean f2 ... -daymean f40 ]}
\]

Apply saves the day. And creates the call above with much less typing.

\[
\text{cdo -yearmean -merge [ -apply,-daymean [ f1 ... f40 ] ]}
\]

Figure 1.2.: Apply keyword simplifies command and execution

In the example in figure 1.2 the resulting call will dramatically save process interaction as well as execution times since the reduction (daymean) is applied on the files first. That means that the merge operator will receive the reduced files and the operations for merging the whole data is saved. For other CDO calls further improvements can be made by adding more arguments to apply (1.3)
A less performant example.

```
cdo -aReduction -anotherReduction -daymean -merge [ f1 ... f40 ]
```

```
cdo -merge -apply,-"aReduction -anotherReduction -daymean" [ f1 ... f40 ]
```

Figure 1.3.: Multi argument apply

**Restrictions:** While the apply keyword can be extremely helpful it has several restrictions (for now!).

- Apply inputs can only be files, wildcards and operators that have 0 inputs and 1 output.
- Apply can not be used as the first CDO operator.
- Apply arguments can only be operators with 1 input and 1 output.
- Grouping inside the Apply argument or input is not allowed.

1.4. Memory Requirements

This section roughly describes the memory requirements of CDO. CDO tries to use as little memory as possible. The smallest unit that is read by all operators is a horizontal field. The required memory depends mainly on the used operators, the data format, the data type and the size of the fields.

The operators have partly very different memory requirements. Many CDO modules like FLDSTAT process one horizontal field at a time. Memory-intensive modules such as ENSSTAT and TIMSTAT require all fields of a time step to be held in memory. Of course, the memory requirements of each operator add up when they are combined. Some operators are parallelized with OpenMP. In multi-threaded mode (see option -P) the memory requirement can increase for these operators. This increase grows with the number of threads used.

The data type determines the number of bytes per value. Single precision floating point data (float) occupies 4 bytes per value. All other data types are read as double precision floats and thus occupy 8 bytes per value. With the CDO option --single all data is read as single precision floats. This can reduce the memory requirement by a factor of 2.

1.5. Horizontal grids

Physical quantities of climate models are typically stored on a horizontal grid. CDO supports structured grids like regular lon/lat or curvilinear grids and also unstructured grids.

1.5.1. Grid area weights

One single point of a horizontal grid represents the mean of a grid cell. These grid cells are typically of different sizes, because the grid points are of varying distance.

Area weights are individual weights for each grid cell. They are needed to compute the area weighted mean or variance of a set of grid cells (e.g. fldmean - the mean value of all grid cells). In CDO the area weights are derived from the grid cell area. If the cell area is not available then it will be computed from the geographical coordinates via spherical triangles. This is only possible if the geographical coordinates of the grid cell corners are available or derivable. Otherwise CDO gives a warning message and uses constant area weights for all grid cells.

The cell area is read automatically from a NetCDF input file if a variable has the corresponding “cell_measures” attribute, e.g.:
If the computed cell area is not desired then the CDO operator setgridarea can be used to set or overwrite the grid cell area.

### 1.5.2. Grid description

In the following situations it is necessary to give a description of a horizontal grid:

- Changing the grid description (operator: setgrid)
- Horizontal interpolation (all remapping operators)
- Generating of variables (operator: const, random)

As now described, there are several possibilities to define a horizontal grid.

#### 1.5.2.1. Predefined grids

Predefined grids are available for global regular, gaussian, HEALPix or icosahedral-hexagonal GME grids.

**Global regular grid:** `global_<DXY>`

`global_<DXY>` defines a global regular lon/lat grid. The grid increment `<DXY>` can be chosen arbitrarily. The longitudes start at `<DXY>/2 - 180°` and the latitudes start at `<DXY>/2 - 90°`.

**Regional regular grid:** `dcw:<CountryCode>[_<DXY>]`

`dcw:<CountryCode>[_<DXY>]` defines a regional regular lon/lat grid from the country code. The default value of the optional grid increment `<DXY>` is 0.1 degree. The ISO two-letter country codes can be found on https://en.wikipedia.org/wiki/ISO_3166-1_alpha-2. For the coordinates of a country CDO uses the DCW (Digital Chart of the World) dataset from GMT. This dataset must be installed on the system and the environment variable `DIR_DCW` must point to it.

**Zonal latitudes:** `zonal_<DY>`

`zonal_<DY>` defines a grid with zonal latitudes only. The latitude increment `<DY>` can be chosen arbitrarily. The latitudes start at `<DY>/2 - 90°`. The boundaries of each latitude are also generated. The number of longitudes is 1. A grid description of this type is needed to calculate the zonal mean (zonmean) for data on an unstructured grid.

**Global regular grid:** `r<NX>x<NY>`

`r<NX>x<NY>` defines a global regular lon/lat grid. The number of the longitudes `<NX>` and the latitudes `<NY>` can be chosen arbitrarily. The longitudes start at 0° with an increment of (360/<NX>)°. The latitudes go from south to north with an increment of (180/<NY>)°.

**One grid point:** `lon=<LON>/lat=<LAT>`

`lon=<LON>/lat=<LAT>` defines a lon/lat grid with only one grid point.
**Full regular Gaussian grid:** \( F^{<\text{XXX}>} \)

\( F^{<\text{XXX}>} \) defines a global regular Gaussian grid. \( \text{XXX} \) specifies the number of latitudes lines between the Pole and the Equator. The longitudes start at 0° with an increment of \((360/\text{nlon})°\). The gaussian latitudes go from north to south.

**Global icosahedral-hexagonal GME grid:** \( \text{gme}^{<\text{NI}>} \)

\( \text{gme}^{<\text{NI}>} \) defines a global icosahedral-hexagonal GME grid. \( \text{NI} \) specifies the number of intervals on a main triangle side.

**HEALPix grid:** \( \text{hp}^{<\text{NSIDE}[\text{b}][<\text{ORDER}>]} \)

HEALPix is an acronym for Hierarchical Equal Area isoLatitude Pixelization of a sphere. \( \text{hp}^{<\text{NSIDE}[\text{b}][<\text{ORDER}>]} \) defines a global HEALPix grid. The \( \text{NSIDE} \) parameter controls the resolution of the pixellization. It is the number of pixels on the side of each of the 12 top-level HEALPix pixels. The total number of grid pixels is \( 12*\text{NSIDE}\times\text{NSIDE} \). \( \text{NSIDE}=1 \) generates the 12 (H=4, K=3) equal sized top-level HEALPix pixels. \( \text{ORDER} \) sets the index ordering convention of the pixels, available are ring (default) or nest ordering. If the parameter \( \text{b} \) is set, the grid cell corners are also calculated.

### 1.5.2.2. Grids from data files

You can use the grid description from another datafile. The format of the datafile and the grid of the data field must be supported by \texttt{CDO}. Use the operator \texttt{`sinfo' to get short informations about your variables and the grids. If there are more then one grid in the datafile the grid description of the first variable will be used. Add the extension \texttt{:`N} to the name of the datafile to select grid number \( \text{N} \).

### 1.5.2.3. SCRIP grids

SCRIP (Spherical Coordinate Remapping and Interpolation Package) uses a common grid description for curvilinear and unstructured grids. For more information about the convention see \[SCRIP\]. This grid description is stored in NetCDF. Therefore it is only available if \texttt{CDO} was compiled with NetCDF support!

SCRIP grid description example of a curvilinear MPIOM [\texttt{MPIOM}] GROB3 grid (only the NetCDF header):

```plaintext
netcdf grob3s {
dimensions:
grid_size = 12120 ;
grid_corners = 4 ;
grid_rank = 2 ;
variables:
  int grid_dims(grid_rank) :
  double grid_center_lat(grid_size) :
    grid_center_lat:units = "degrees" ;
    grid_center_lat:bounds = "grid_corner_lat" ;
  double grid_center_lon(grid_size) :
    grid_center_lon:units = "degrees" ;
    grid_center_lon:bounds = "grid_corner_lon" ;
  int grid_imask(grid_size) :
    grid_imask:units = "unitless" ;
    grid_imask:coordinates = "grid_center_lon grid_center_lat" ;
  double grid_corner_lat(grid_size, grid_corners) :
    grid_corner_lat:units = "degrees" ;
  double grid_corner_lon(grid_size, grid_corners) :
    grid_corner_lon:units = "degrees" ;
}
```

---

19
1.5.2.4. CDO grids

All supported grids can also be described with the CDO grid description. The following keywords can be used to describe a grid:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gridtype</td>
<td>STRING</td>
<td>Type of the grid (gaussian, lonlat, curvilinear, unstructured).</td>
</tr>
<tr>
<td>gridsize</td>
<td>INTEGER</td>
<td>Size of the grid.</td>
</tr>
<tr>
<td>xsizex</td>
<td>INTEGER</td>
<td>Size in x direction (number of longitudes).</td>
</tr>
<tr>
<td>ysizey</td>
<td>INTEGER</td>
<td>Size in y direction (number of latitudes).</td>
</tr>
<tr>
<td>xvalsx</td>
<td>FLOAT ARRAY</td>
<td>X values of the grid cell center.</td>
</tr>
<tr>
<td>yvalsy</td>
<td>FLOAT ARRAY</td>
<td>Y values of the grid cell center.</td>
</tr>
<tr>
<td>nvertex</td>
<td>INTEGER</td>
<td>Number of the vertices for all grid cells.</td>
</tr>
<tr>
<td>xbounds</td>
<td>FLOAT ARRAY</td>
<td>X bounds of each gridbox.</td>
</tr>
<tr>
<td>ybounds</td>
<td>FLOAT ARRAY</td>
<td>Y bounds of each gridbox.</td>
</tr>
<tr>
<td>xfirst, xinc</td>
<td>FLOAT, FLOAT</td>
<td>Macros to define xvals with a constant increment,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>xfirst is the x value of the first grid cell center.</td>
</tr>
<tr>
<td>yfirst, yinc</td>
<td>FLOAT, FLOAT</td>
<td>Macros to define yvals with a constant increment,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>yfirst is the y value of the first grid cell center.</td>
</tr>
<tr>
<td>xunits</td>
<td>STRING</td>
<td>units of the x axis</td>
</tr>
<tr>
<td>yunits</td>
<td>STRING</td>
<td>units of the y axis</td>
</tr>
</tbody>
</table>

Which keywords are necessary depends on the gridtype. The following table gives an overview of the default values or the size with respect to the different grid types.

<table>
<thead>
<tr>
<th>gridtype</th>
<th>lonlat</th>
<th>gaussian</th>
<th>projection</th>
<th>curvilinear</th>
<th>unstructured</th>
</tr>
</thead>
<tbody>
<tr>
<td>gridsize</td>
<td>nlon</td>
<td>nlon</td>
<td>nx</td>
<td>nlon</td>
<td>gridsize</td>
</tr>
<tr>
<td>xsizex</td>
<td>nlat</td>
<td>nlat</td>
<td>ny</td>
<td>nlat</td>
<td>gridsize</td>
</tr>
<tr>
<td>yvalsy</td>
<td>ysize</td>
<td>ysize</td>
<td>ysize</td>
<td>xsize</td>
<td>gridsize</td>
</tr>
<tr>
<td>nvertex</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>4</td>
<td>nv</td>
</tr>
<tr>
<td>xbounds</td>
<td>2*xsize</td>
<td>2*xsize</td>
<td>2*xsize</td>
<td>4*gridsize</td>
<td>nv*gridsize</td>
</tr>
<tr>
<td>ybounds</td>
<td>2*ysize</td>
<td>2*ysize</td>
<td>2*ysize</td>
<td>4*gridsize</td>
<td>nv*gridsize</td>
</tr>
<tr>
<td>xunits</td>
<td>degrees</td>
<td>degrees</td>
<td>m</td>
<td>degrees</td>
<td></td>
</tr>
<tr>
<td>yunits</td>
<td>degrees</td>
<td>degrees</td>
<td>m</td>
<td>degrees</td>
<td></td>
</tr>
</tbody>
</table>

The keywords nvertex, xbounds and ybounds are optional if area weights are not needed. The grid cell corners xbounds and ybounds have to rotate counterclockwise.

**CDO grid description example of a T21 gaussian grid:**

```plaintext
gridtype = gaussian
xsizex = 64
ysizey = 32
xfirst = 0
xinc = 5.625
yvalsx = 85.76  80.27  74.75  69.21  63.68  58.14  52.61  47.07
41.53  36.00  30.46  24.92  19.38  13.84  8.31  2.77
−2.77  −8.31 −13.84 −19.38 −24.92 −30.46 −36.00 −41.53
−47.07 −52.61 −58.14 −63.68 −69.21 −74.75 −80.27 −85.76
```

**CDO grid description example of a global regular grid with 60x30 points:**

```plaintext
gridtype = lonlat
xsizex = 60
ysizey = 30
```
The description for a projection is somewhat more complicated. Use the first section to describe the coordinates of the projection with the above keywords. Add the keyword \texttt{grid\_mapping\_name} to describe the mapping between the given coordinates and the true latitude and longitude coordinates. \texttt{grid\_mapping\_name} takes a string value that contains the name of the projection. A list of attributes can be added to define the mapping. The name of the attributes depend on the projection. The valid names of the projection and their attributes follow the NetCDF CF-Convention.

\texttt{CDO} supports the special grid mapping attribute \texttt{proj\_params}. These parameter will be passed directly to the PROJ library to generate the geographic coordinates if needed.

The geographic coordinates of the following projections can be generated without the attribute \texttt{proj\_params}, if all other attributes are available:

- \texttt{rotated\_latitude\_longitude}
- \texttt{lambert\_conformal\_conic}
- \texttt{lambert\_azimuthal\_equal\_area}
- \texttt{sinusoidal}
- \texttt{polar\_stereographic}

It is recommend to set the attribute \texttt{proj\_params} also for the above projections to make sure all PROJ parameter are set correctly.

Here is an example of a \texttt{CDO} grid description using the attribute \texttt{proj\_params} to define the PROJ parameter of a polar stereographic projection:

\begin{verbatim}
gridtype = projection
xsize = 11
ysize = 11
xunits = 'meter'
yunits = 'meter'
xfirst = -638000
xinc = 150
yfirst = -3349350
yinc = 150
grid_mapping = crs
grid_mapping_name = polar_stereographic
proj_params = '+proj=stere +lon_0=-45 +lat_ts=70 +lat_0=90 +x_0=0 +y_0=0'
\end{verbatim}

The result is the same as using the CF conform Grid Mapping Attributes:

\begin{verbatim}
gridtype = projection
xsize = 11
ysize = 11
xunits = 'meter'
yunits = 'meter'
xfirst = -638000
xinc = 150
yfirst = -3349350
yinc = 150
grid_mapping = crs
grid_mapping_name = polar_stereographic
straight_vertical_longitude_from_pole = -45.
standard_parallel = 70.
latitude_of_projection_origin = 90.
false_easting = 0.
false_northing = 0.
\end{verbatim}

\texttt{CDO} grid description example of a regional rotated lon/lat grid:
Example **CDO** descriptions of a curvilinear and an unstructured grid can be found in Appendix D.

### 1.5.3. ICON - Grid File Server

The geographic coordinates of the ICON model are located on an unstructured grid. This grid is stored in a separate grid file independent of the model data. The grid files are made available to the general public via a file server. Furthermore, these grid files are located at DKRZ under `/pool/data/ICON/grids`.

With the **CDO** function `setgrid,<gridfile>` this grid information can be added to the data if needed. Here is an example:

```
cdo sellonlatbox,-20,60,10,70 -setgrid,<path_to_gridfile> icondatafile result
```

ICON model data in NetCDF format contains the global attribute `grid_file_uri`. This attribute contains a link to the appropriate grid file on the ICON grid file server. If the global attribute `grid_file_uri` is present and valid, the grid information can be added automatically. The `setgrid` function is then no longer required. The environment variable `CDO_DOWNLOAD_PATH` can be used to select a directory for storing the grid file. If this environment variable is set, the grid file will be automatically downloaded from the grid file server to this directory if needed. If the grid file already exists in the current directory, the environment variable does not need to be set.

If the grid files are available locally, like at DKRZ, they do not need to be fetched from the grid file server. Use the environment variable `CDO_ICON_GRIDS` to set the root directory of the ICON grids. Here is an example for the ICON grids at DKRZ:

```
CDO_ICON_GRIDS=/pool/data/ICON
```

### 1.6. Z-axis description

Sometimes it is necessary to change the description of a z-axis. This can be done with the operator `setzaxis`. This operator needs an ASCII formatted file with the description of the z-axis. The following keywords can be used to describe a z-axis:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>zaxistype</td>
<td>STRING</td>
<td>type of the z-axis</td>
</tr>
<tr>
<td>size</td>
<td>INTEGER</td>
<td>number of levels</td>
</tr>
<tr>
<td>levels</td>
<td>FLOAT ARRAY</td>
<td>values of the levels</td>
</tr>
<tr>
<td>lbounds</td>
<td>FLOAT ARRAY</td>
<td>lower level bounds</td>
</tr>
<tr>
<td>ubounds</td>
<td>FLOAT ARRAY</td>
<td>upper level bounds</td>
</tr>
<tr>
<td>vctsize</td>
<td>INTEGER</td>
<td>number of vertical coordinate parameters</td>
</tr>
<tr>
<td>vct</td>
<td>FLOAT ARRAY</td>
<td>vertical coordinate table</td>
</tr>
</tbody>
</table>

The keywords `lbounds` and `ubounds` are optional. `vctsize` and `vct` are only necessary to define hybrid model levels.
Introduction

Available z-axis types:

<table>
<thead>
<tr>
<th>Z-axis type</th>
<th>Description</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>surface</td>
<td>Surface</td>
<td></td>
</tr>
<tr>
<td>pressure</td>
<td>Pressure level</td>
<td>pascal</td>
</tr>
<tr>
<td>hybrid</td>
<td>Hybrid model level</td>
<td></td>
</tr>
<tr>
<td>height</td>
<td>Height above ground</td>
<td>meter</td>
</tr>
<tr>
<td>depth_below_sea</td>
<td>Depth below sea level</td>
<td>meter</td>
</tr>
<tr>
<td>depth_below_land</td>
<td>Depth below land surface</td>
<td>centimeter</td>
</tr>
<tr>
<td>isentropic</td>
<td>Isentropic (theta) level</td>
<td>kelvin</td>
</tr>
</tbody>
</table>

Z-axis description example for pressure levels 100, 200, 500, 850 and 1000 hPa:

```
zaxistype = pressure
size = 5
levels = 10000 20000 50000 85000 100000
```

Z-axis description example for ECHAM5 L19 hybrid model levels:

```
zaxistype = hybrid
size = 19
levels = 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19
vctsize = 40
vct = 0 2000 4000 6046.92578 8267.92578 10609.5117 12851.1016 14698.5
15861.125 16116.2383 15356.9258 13621.4609 11101.5625 8127.14453
5125.14062 2549.96875 783.195068 0 0 0
0 0 0 0.000338993268 0.00335718691 0.0130700432 0.0340771675
0.0706498027 0.12591666 0.201195419 0.295519829 0.405408859
0.524931908 0.646107674 0.759697914 0.856437683 0.928747177
0.972985268 0.992281914 1
```

Note that the vctsize is twice the number of levels plus two and the vertical coordinate table must be specified for the level interfaces.

1.7. Time axis

A time axis describes the time for every timestep. Two time axis types are available: absolute time and relative time axis. CDO tries to maintain the actual type of the time axis for all operators.

1.7.1. Absolute time

An absolute time axis has the current time to each time step. It can be used without knowledge of the calendar. This is preferably used by climate models. In NetCDF files the absolute time axis is represented by the unit of the time: "day as %Y%m%d.%f".

1.7.2. Relative time

A relative time is the time relative to a fixed reference time. The current time results from the reference time and the elapsed interval. The result depends on the calendar used. CDO supports the standard Gregorian, proleptic Gregorian, 360 days, 365 days and 366 days calendars. The relative time axis is preferably used by numerical weather prediction models. In NetCDF files the relative time axis is represented by the unit of the time: "time-units since reference-time", e.g "days since 1989-6-15 12:00".
1.7.3. Conversion of the time

Some programs which work with NetCDF data can only process relative time axes. Therefore it may be necessary to convert from an absolute into a relative time axis. This conversion can be done for each operator with the CDO option `-r`. To convert a relative into an absolute time axis use the CDO option `-a`.

1.8. Parameter table

A parameter table is an ASCII formatted file to convert code numbers to variable names. Each variable has one line with its code number, name and a description with optional units in a blank separated list. It can only be used for GRIB, SERVICE, EXTRA and IEG formatted files. The CDO option `-t <partab>` sets the default parameter table for all input files. Use the operator `setpartab` to set the parameter table for a specific file.

Example of a CDO parameter table:

<table>
<thead>
<tr>
<th>Code</th>
<th>Code</th>
<th>Name</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>134</td>
<td>aps</td>
<td>surface pressure</td>
<td>[Pa]</td>
</tr>
<tr>
<td>141</td>
<td>sn</td>
<td>snow depth</td>
<td>[m]</td>
</tr>
<tr>
<td>147</td>
<td>shfl</td>
<td>latent heat flux</td>
<td>[W/m²*2]</td>
</tr>
<tr>
<td>172</td>
<td>slm</td>
<td>land sea mask</td>
<td></td>
</tr>
<tr>
<td>175</td>
<td>albedo</td>
<td>surface albedo</td>
<td></td>
</tr>
<tr>
<td>211</td>
<td>siced</td>
<td>ice depth</td>
<td>[m]</td>
</tr>
</tbody>
</table>

1.9. Missing values

Missing values are data points that are missing or invalid. Such data points are treated in a different way than valid data. Most CDO operators can handle missing values in a smart way. But if the missing value is within the range of valid data, it can lead to incorrect results. This applies to all arithmetic operations, but especially to logical operations when the missing value is 0 or 1.

The default missing value for GRIB, SERVICE, EXTRA and IEG files is $-9.99999999999993 	imes 10^{-33}$. The CDO option `-m <missval>` overwrites the default missing value. In NetCDF files the variable attribute `"_FillValue"` is used as a missing value. The operator `setmissval` can be used to set a new missing value.

The CDO use of the missing value is shown in the following tables, where one table is printed for each operation. The operations are applied to arbitrary numbers $a$, $b$, the special case $0$, and the missing value $\text{miss}$. For example the table named "addition" shows that the sum of an arbitrary number $a$ and the missing value is the missing value, and the table named "multiplication" shows that $0$ multiplied by missing value results in $0$.  

24
The handling of missing values by the operations "minimum" and "maximum" may be surprising, but the
definition given here is more consistent with that expected in practice. Mathematical functions (e.g. \textit{log},
\textit{sqrt}, etc.) return the missing value if an argument is the missing value or an argument is out of range.

All statistical functions ignore missing values, treading them as not belonging to the sample, with the
side-effect of a reduced sample size.

### 1.9.1. Mean and average

An artificial distinction is made between the notions mean and average. The mean is regarded as a
statistical function, whereas the average is found simply by adding the sample members and dividing the
result by the sample size. For example, the mean of 1, 2, \textit{miss} and 3 is \((1 + 2 + \textit{miss} + 3)/3 = 2\), whereas the
average is \((1 + 2 + \textit{miss} + 3)/4 = \textit{miss}/4 = \textit{miss}\). If there are no missing values in the sample, the average
and mean are identical.

### 1.10. Percentile

There is no standard definition of percentile. All definitions yield to similar results when the number of
values is very large. The following percentile methods are available in \textsc{CDO}:
The percentile method can be selected with the CDO option --percentile. The Nearest Rank method is the default percentile method in CDO.

The different percentile methods can lead to different results, especially for small number of data values. Consider the ordered list \{15, 20, 35, 40, 50, 55\}, which contains six data values. Here is the result for the 30th, 40th, 50th, 75th and 100th percentiles of this list using the different percentile methods:

<table>
<thead>
<tr>
<th>Percentile</th>
<th>nrank</th>
<th>nist</th>
<th>rtype8</th>
<th>numpy</th>
<th>numpy_lower</th>
<th>numpy_higher</th>
<th>numpy_nearest</th>
</tr>
</thead>
<tbody>
<tr>
<td>30th</td>
<td>20</td>
<td>21.5</td>
<td>23.5</td>
<td>27.5</td>
<td>20</td>
<td>35</td>
<td>35</td>
</tr>
<tr>
<td>40th</td>
<td>35</td>
<td>32</td>
<td>33</td>
<td>35</td>
<td>35</td>
<td>40</td>
<td>40</td>
</tr>
<tr>
<td>50th</td>
<td>35</td>
<td>37.5</td>
<td>37.5</td>
<td>37.5</td>
<td>35</td>
<td>40</td>
<td>40</td>
</tr>
<tr>
<td>75th</td>
<td>50</td>
<td>51.25</td>
<td>50.42</td>
<td>47.5</td>
<td>40</td>
<td>50</td>
<td>50</td>
</tr>
<tr>
<td>100th</td>
<td>55</td>
<td>55</td>
<td>55</td>
<td>55</td>
<td>55</td>
<td>55</td>
<td>55</td>
</tr>
</tbody>
</table>

1.10.1. Percentile over timesteps

The amount of data for time series can be very large. All data values need to held in memory to calculate the percentile. The percentile over timesteps uses a histogram algorithm, to limit the amount of required memory. The default number of histogram bins is 101. That means the histogram algorithm is used, when the dataset has more than 101 time steps. The default can be overridden by setting the environment variable CDO_PCTL_NBINS to a different value. The histogram algorithm is implemented only for the Nearest Rank method.

1.11. Regions

The CDO operators maskregion and selregion can be used to mask and select regions. For this purpose, the region needs to be defined by the user. In CDO there are two possibilities to define regions.

One possibility is to define the regions with an ASCII file. Each region is defined by a polygon. Each line of the polygon contains the longitude and latitude coordinates of a point. A description file for regions can contain several polygons, these must be separated by a line with the character &.

Here is a simple example of a polygon for a box with longitudes from 120W to 90E and latitudes from 20N to 20S:

```
120 20
120 -20
270 -20
270 20
```

With the second option, predefined regions can be used via country codes. The region is specified with dcw:<CountryCode>. Country codes can be combined with the plus sign.
Here is an example to select the region Spain and Portugal:

cdo selregion,dcw:ES+PT infile outfile

The ISO two-letter country codes can be found on https://en.wikipedia.org/wiki/ISO_3166-1_alpha-2. For the coordinates of a country **CDO** uses the DCW (Digital Chart of the World) dataset from **GMT**. This dataset must be installed on the system and the environment variable \texttt{DIR\_DCW} must point to it.
2. Reference manual

This section gives a description of all operators. Related operators are grouped to modules. For easier description all single input files are named infile or infile1, infile2, etc., and an arbitrary number of input files are named infiles. All output files are named outfile or outfile1, outfile2, etc. Further the following notion is introduced:

\( i(t) \) Timestep \( t \) of infile

\( i(t,x) \) Element number \( x \) of the field at timestep \( t \) of infile

\( o(t) \) Timestep \( t \) of outfile

\( o(t,x) \) Element number \( x \) of the field at timestep \( t \) of outfile
2.1. Information

This section contains modules to print information about datasets. All operators print there results to standard output.

Here is a short overview of all operators in this section:

- **info**: Dataset information listed by parameter identifier
- **infon**: Dataset information listed by parameter name
- **map**: Dataset information and simple map
- **sinfo**: Short information listed by parameter identifier
- **sinfon**: Short information listed by parameter name
- **diff**: Compare two datasets listed by parameter id
- **diffn**: Compare two datasets listed by parameter name
- **npar**: Number of parameters
- **nlevel**: Number of levels
- **nyear**: Number of years
- **nmon**: Number of months
- **ndate**: Number of dates
- **ntime**: Number of timesteps
- **ngridpoints**: Number of gridpoints
- **ngrids**: Number of horizontal grids
- **showformat**: Show file format
- **showcode**: Show code numbers
- **showname**: Show variable names
- **showstdname**: Show standard names
- **showlevel**: Show levels
- **showltype**: Show GRIB level types
- **showyear**: Show years
- **showmon**: Show months
- **showdate**: Show date information
- **showtime**: Show time information
- **showtimestamp**: Show timestamp
- **showattribute**: Show a global attribute or a variable attribute
- **partab**: Parameter table
- **codetab**: Parameter code table
- **griddes**: Grid description
- **zaxisdes**: Z-axis description
- **vct**: Vertical coordinate table
2.1.1. INFO - Information and simple statistics

Synopsis

\(<\text{operator}>\) infiles

Description

This module writes information about the structure and contents for each field of all input files to standard output. A field is a horizontal layer of a data variable. All input files need to have the same structure with the same variables on different timesteps. The information displayed depends on the chosen operator.

Operators

info Dataset information listed by parameter identifier
Prints information and simple statistics for each field of all input datasets. For each field the operator prints one line with the following elements:
- Date and Time
- Level, Gridsize and number of Missing values
- Minimum, Mean and Maximum
  The mean value is computed without the use of area weights!
- Parameter identifier

infon Dataset information listed by parameter name
The same as operator info but using the name instead of the identifier to label the parameter.

map Dataset information and simple map
Prints information, simple statistics and a map for each field of all input datasets. The map will be printed only for fields on a regular lon/lat grid.

Example

To print information and simple statistics for each field of a dataset use:

\[\text{cdo infon infile}\]

This is an example result of a dataset with one 2D parameter over 12 timesteps:

<table>
<thead>
<tr>
<th></th>
<th>Date</th>
<th>Time</th>
<th>Level</th>
<th>Size</th>
<th>Miss</th>
<th>Minimum</th>
<th>Mean</th>
<th>Maximum</th>
<th>Name</th>
</tr>

</tbody>
</table>
2.1.2. SINFO - Short information

Synopsis

<operator> infiles

Description

This module writes information about the structure of infiles to standard output. infiles is an arbitrary number of input files. All input files need to have the same structure with the same variables on different timesteps. The information displayed depends on the chosen operator.

Operators

sinfo Short information listed by parameter identifier
Prints short information of a dataset. The information is divided into 4 sections. Section 1 prints one line per parameter with the following information:

- institute and source
- time c=constant v=varying
- type of statistical processing
- number of levels and z-axis number
- horizontal grid size and number
- data type
- parameter identifier

Section 2 and 3 gives a short overview of all grid and vertical coordinates. And the last section contains short information of the time coordinate.

sinfon Short information listed by parameter name
The same as operator sinfo but using the name instead of the identifier to label the parameter.

Example

To print short information of a dataset use:

```
cdo sinfon infile
```

This is the result of an ECHAM5 dataset with 3 parameter over 12 timesteps:

```
-1 : Institute Source T Steptype Levels Num Points Num Dtype : Name
  1 : MPIMET ECHAM5 c instant 1 1 2048 1 F32 : GEOF
  2 : MPIMET ECHAM5 v instant 4 2 2048 1 F32 : T
  3 : MPIMET ECHAM5 v instant 1 1 2048 1 F32 : TSURF

Grid coordinates :
  1 : gaussian : points=2048 (64x32) F16

      longitude : 0 to 354.375 by 5.625 degrees_east circular
      latitude : 85.7606 to −85.7606 degrees_north

Vertical coordinates :
  1 : surface : levels=1
  2 : pressure : levels=4

      level : 92500 to 20000 Pa

Time coordinate :

      time : 12 steps
```

YYYY-MM-DD hh:mm:ss YYYY-MM-DD hh:mm:ss YYYY-MM-DD hh:mm:ss YYYY-MM-DD hh:mm:ss
1987−01−31 12:00:00 1987−02−28 12:00:00 1987−03−31 12:00:00 1987−04−30 12:00:00
1987−05−31 12:00:00 1987−06−30 12:00:00 1987−07−31 12:00:00 1987−08−31 12:00:00
1987−09−30 12:00:00 1987−10−31 12:00:00 1987−11−30 12:00:00 1987−12−31 12:00:00
2.1.3. **DIFF - Compare two datasets field by field**

**Synopsis**

```
<operator>[,options] infile1 infile2
```

**Description**

Compares the contents of two datasets field by field. The input datasets need to have the same structure and its fields need to have the same header information and dimensions. Try the option *names* if the number of variables differ. Exit status is 0 if inputs are the same and 1 if they differ.

**Operators**

- **diff**: Compare two datasets listed by parameter id
  Provides statistics on differences between two datasets. For each pair of fields the operator prints one line with the following information:
  - Date and Time
  - Level, Gridsize and number of Missing values
  - Number of different values
  - Occurrence of coefficient pairs with different signs (S)
  - Occurrence of zero values (Z)
  - Maxima of absolute difference of coefficient pairs
  - Maxima of relative difference of non-zero coefficient pairs with equal signs
  - Parameter identifier

  \[
  Abs\text{diff}(t, x) = |i_1(t, x) - i_2(t, x)|
  \]

  \[
  Rel\text{diff}(t, x) = \frac{|i_1(t, x) - i_2(t, x)|}{\text{max}(|i_1(t, x)|, |i_2(t, x)|)}
  \]

- **diffn**: Compare two datasets listed by parameter name
  The same as operator *diff*. Using the name instead of the identifier to label the parameter.

**Parameter**

- **maxcount**: INTEGER  
  Stop after maxcount different fields

- **abslim**: FLOAT  
  Limit of the maximum absolute difference (default: 0)

- **rellim**: FLOAT  
  Limit of the maximum relative difference (default: 1)

- **names**: STRING  
  Consideration of the variable names of only one input file (left/right) or the intersection of both (intersect).

**Example**

To print the difference for each field of two datasets use:

```
cdo diffn infile1 infile2
```

This is an example result of two datasets with one 2D parameter over 12 timesteps:
2.1.4. NINFO - Print the number of parameters, levels or times

Synopsis

<operator> infile

Description

This module prints the number of variables, levels or times of the input dataset.

Operators

- **npar**
  Number of parameters
  Prints the number of parameters (variables).

- **nlevel**
  Number of levels
  Prints the number of levels for each variable.

- **nyear**
  Number of years
  Prints the number of different years.

- **nmon**
  Number of months
  Prints the number of different combinations of years and months.

- **ndate**
  Number of dates
  Prints the number of different dates.

- **ntime**
  Number of timesteps
  Prints the number of timesteps.

- **ngridpoints**
  Number of gridpoints
  Prints the number of gridpoints for each variable.

- **ngrids**
  Number of horizontal grids
  Prints the number of horizontal grids.

Example

To print the number of parameters (variables) in a dataset use:

```
cdo npar infile
```

To print the number of months in a dataset use:

```
cdo nmon infile
```
2.1.5. SHOWINFO - Show variables, levels or times

Synopsis
<operator> infile

Description
This module prints the format, variables, levels or times of the input dataset.

Operators

- **showformat**: Show file format
  Prints the file format of the input dataset.
- **showcode**: Show code numbers
  Prints the code number of all variables.
- **showname**: Show variable names
  Prints the name of all variables.
- **showstdname**: Show standard names
  Prints the standard name of all variables.
- **showlevel**: Show levels
  Prints all levels for each variable.
- **showltype**: Show GRIB level types
  Prints the GRIB level type for all z-axes.
- **showyear**: Show years
  Prints all years.
- **showmon**: Show months
  Prints all months.
- **showdate**: Show date information
  Prints date information of all timesteps (format YYYY-MM-DD).
- **showtime**: Show time information
  Prints time information of all timesteps (format hh:mm:ss).
- **showtimestamp**: Show timestamp
  Prints timestamp of all timesteps (format YYYY-MM-DDThh:mm:ss).

Example
To print the code number of all variables in a dataset use:

```
cdo showcode infile
```

This is an example result of a dataset with three variables:

```
129 130 139
```

To print all months in a dataset use:

```
cdo showmon infile
```

This is an example result of a dataset with an annual cycle:

```
1 2 3 4 5 6 7 8 9 10 11 12
```
2.1.6. SHOWATTRIBUTE - Show attributes

Synopsis

    showattribute[,attributes]  infile

Description

This operator prints the attributes of the data variables of a dataset.

Each attribute has the following structure:

    [var__nm@][att__nm]

    var__nm   Variable name (optional). Example: pressure
    att__nm   Attribute name (optional). Example: units

The value of var__nm is the name of the variable containing the attribute (named att__nm) that you want to print. Use wildcards to print the attribute att__nm of more than one variable. A value of var__nm of '*' will print the attribute att__nm of all data variables. If var__nm is missing then att__nm refers to a global attribute.

The value of att__nm is the name of the attribute you want to print. Use wildcards to print more than one attribute. A value of att__nm of '*' will print all attributes.

Parameter

    attributes  STRING  Comma-separated list of attributes.
### 2.1.7. FILEDES - Dataset description

#### Synopsis

```markdown
<operator> infile
```

#### Description

This module provides operators to print meta information about a dataset. The printed meta-data depends on the chosen operator.

#### Operators

- **partab** Parameter table
  - Prints all available meta information of the variables.

- **codetab** Parameter code table
  - Prints a code table with a description of all variables. For each variable the operator prints one line listing the code, name, description and units.

- **griddes** Grid description
  - Prints the description of all grids.

- **zaxisdes** Z-axis description
  - Prints the description of all z-axes.

- **vct** Vertical coordinate table
  - Prints the vertical coordinate table.

#### Example

Assume all variables of the dataset are on a Gaussian N16 grid. To print the grid description of this dataset use:

```bash
cdo griddes infile
```

**Result:**

```
gridtype : gaussian
gridsize : 2048
xname : lon
xlongname : longitude
xunits : degrees_east
yname : lat
ylongname : latitude
yunits : degrees_north
xsize : 64
ysize : 32
xfirst : 0
xinc : 5.625
yvals : 85.76058 80.26877 74.74454 69.21297 63.67863 58.1429 52.6065
        47.06964 41.53246 35.99507 30.4575 24.91992 19.38223 13.84448
      -58.1429 -63.67863 -69.21297 -74.74454 -80.26877 -85.76058
```
2.2. File operations

This section contains modules to perform operations on files.

Here is a short overview of all operators in this section:

- **apply**: Apply operators on each input file.
- **copy**: Copy datasets
- **clone**: Clone datasets
- **cat**: Concatenate datasets
- **tee**: Duplicate a data stream
- **pack**: Pack data
- **bitrounding**: Bit rounding
- **replace**: Replace variables
- **duplicate**: Duplicates a dataset
- **mergegrid**: Merge grid
- **merge**: Merge datasets with different fields
- **mergetime**: Merge datasets sorted by date and time
- **splitcode**: Split code numbers
- **splitparam**: Split parameter identifiers
- **splitname**: Split variable names
- **splitlevel**: Split levels
- **splitgrid**: Split grids
- **splitzaxis**: Split z-axes
- **splitstabnum**: Split parameter table numbers
- **splithour**: Split hours
- **splitday**: Split days
- **splitseas**: Split seasons
- **splityear**: Split years
- **splityearmon**: Split in years and months
- **splitmon**: Split months
- **splitsel**: Split time selection
- **distgrid**: Distribute horizontal grid
- **collgrid**: Collect horizontal grid
2.2.1. APPLY - Apply operators

Synopsis

apply,operators infiles

Description

The apply utility runs the named operators on each input file. The input files must be enclosed in square brackets. This utility can only be used on a series of input files. These are all operators with more than one input file (infiles). Here is an incomplete list of these operators: copy, cat, merge, mergetime, select, ENSSTAT. The parameter operators is a blank-separated list of CDO operators. Use quotation marks if more than one operator is needed. Each operator may have only one input and output stream.

Parameter

operators STRING Blank-separated list of CDO operators.

Example

Suppose we have multiple input files with multiple variables on different time steps. The input files contain the variables U and V, among others. We are only interested in the absolute windspeed on all time steps. Here is the standard CDO solution for this task:

```
cdo expr,wind="sqrt(u*u+v*v)" -mergetime infile1 infile2 infile3 outfile
```

This first joins all the time steps together and then calculates the wind speed. If there are many variables in the input files, this procedure is ineffective. In this case it is better to first calculate the wind speed:

```
cdo mergetime -expr,wind="sqrt(u*u+v*v)" infile1
   -expr,wind="sqrt(u*u+v*v)" infile2
   -expr,wind="sqrt(u*u+v*v)" infile3 outfile
```

However, this can quickly become very confusing with more than 3 input files. The apply operator solves this problem:

```
cdo mergetime -apply,-expr,wind="sqrt(u*u+v*v)" [ infile1 infile2 infile3 ] outfile
```

Another example is the calculation of the mean value over several input files with ensmean. The input files contain several variables, but we are only interested in the variable named XXX:

```
cdo ensmean -apply,-selname,XXX [ infile1 infile2 infile3 ] outfile
```
2.2.2. COPY - Copy datasets

Synopsis

<operator> infiles outfile

Description

This module contains operators to copy, clone or concatenate datasets. infiles is an arbitrary number of input files. All input files need to have the same structure with the same variables on different timesteps.

Operators

- **copy**  
  Copy datasets  
  Copies all input datasets to outfile.

- **clone**  
  Clone datasets  
  Copies all input datasets to outfile. In contrast to the copy operator, clone tries not to change the input data. GRIB records are neither decoded nor decompressed.

- **cat**  
  Concatenate datasets  
  Concatenates all input datasets and appends the result to the end of outfile. If outfile does not exist it will be created.

Example

To change the format of a dataset to NetCDF use:

```
cdo -f nc copy infile outfile.nc
```

Add the option '-r' to create a relative time axis, as is required for proper recognition by GrADS or Ferret:

```
cdo -r -f nc copy infile outfile.nc
```

To concatenate 3 datasets with different timesteps of the same variables use:

```
cdo copy infile1 infile2 infile3 outfile
```

If the output dataset already exists and you wish to extend it with more timesteps use:

```
cdo cat infile1 infile2 infile3 outfile
```
2.2.3. TEE - Duplicate a data stream and write it to file

Synopsis

```
tee, outfile2 infile outfile1
```

Description

This operator copies the input dataset to `outfile1` and `outfile2`. The first output stream in `outfile1` can be further processed with other cdo operators. The second output `outfile2` is written to disk. It can be used to store intermediate results to a file.

Parameter

`outfile2` STRING Destination filename for the copy of the input file

Example

To compute the daily and monthly average of a dataset use:

```
cdo monavg -tee, outfile_dayavg dayavg infile outfile_monavg
```

2.2.4. PACK - Pack data

Synopsis

```
pack infile outfile
```

Description

Packing reduces the data volume by reducing the precision of the stored numbers. It is implemented using the NetCDF attributes `add_offset` and `scale_factor`. The operator `pack` calculates the attributes `add_offset` and `scale_factor` for all variables. The default data type for all variables is automatically changed to 16-bit integer. Use the CDO option `-b` to change the data type to a different integer precision, if needed. Missing values are automatically transformed to the current data type.
2.2.5. BITROUNDING - Bit rounding

Synopsis

`bitrounding[,params] infile outfile`

Description

This operator calculates for each field the number of necessary mantissa bits to get a certain information level in the data. With this number of significant bits (`numbits`) a rounding of the data is performed. This allows the data to be compressed to a higher level.

The default value of the information level is 0.9999 and can be adjusted with the parameter `inflevel`. That means 99.99% of the information in the mantissa bits is preserved.

Alternatively, the number of significant bits can be set for all variables with the `numbits` parameter. Furthermore, `numbits` can be assigned for each variable via the filename parameter. In this case, `numbits` is still calculated for all variables if they are not present in the file.

The analysis of the bit information is based on the Julia library `BitInformation.jl`. The procedure to derive the number of significant mantissa bits was adapted from the Python library `xbitinfo`. Quantize to the number of mantissa bits is done with IEEE rounding using code from NetCDF 4.9.0.

Currently only 32-bit float data is rounded. Data with missing values are not yet supported for the calculation of significant bits.

Parameter

- `inflevel` FLOAT Information level (0 - 1) [default: 0.9999]
- `addbits` INTEGER Add bits to the number of significant bits [default: 0]
- `minbits` INTEGER Minimum value of the number of bits [default: 1]
- `maxbits` INTEGER Maximum value of the number of bits [default: 23]
- `numsteps` INTEGER Set to 1 to run the calculation only in the first time step
- `numbits` INTEGER Set number of significant bits
- `printbits` BOOL Print max. number of bits per variable of 1st timestep to stdout [format: name=numbits]
- `filename` STRING Read number of significant bits per variable from file [format: name=numbits]

Example

Apply bit rounding to all 32-bit float fields, preserving 99.9% of the information, followed by compression and storage to NetCDF4:

```
cdo -f nc4 -z zip bitrounding,inflevel=0.999 infile outfile
```

Add the option `-v` to view used number of mantissa bits for each field:

```
cdo -v -f nc4 -z zip bitrounding,inflevel=0.999 infile outfile
```
2.2.6. REPLACE - Replace variables

Synopsis

\texttt{replace \textit{infile1} \textit{infile2} \textit{outfile}}

Description

This operator replaces variables in \textit{infile1} by variables from \textit{infile2} and write the result to \textit{outfile}. Both input datasets need to have the same number of timesteps. All variable names may only occur once!

Example

Assume the first input dataset \textit{infile1} has three variables with the names \texttt{geosp}, \texttt{t} and \texttt{tslm1} and the second input dataset \textit{infile2} has only the variable \texttt{tslm1}. To replace the variable \texttt{tslm1} in \textit{infile1} by \texttt{tslm1} from \textit{infile2} use:

\begin{verbatim}
cdo replace infile1 infile2 outfile
\end{verbatim}

2.2.7. DUPLICATE - Duplicates a dataset

Synopsis

\texttt{duplicate[,\textit{ndup}] \textit{infile} \textit{outfile}}

Description

This operator duplicates the contents of \textit{infile} and writes the result to \textit{outfile}. The optional parameter sets the number of duplicates, the default is 2.

Parameter

\texttt{\textit{ndup}} INTEGER Number of duplicates, default is 2.

2.2.8. MERGEGRID - Merge grid

Synopsis

\texttt{mergegrid \textit{infile1} \textit{infile2} \textit{outfile}}

Description

Merges grid points of all variables from \textit{infile2} to \textit{infile1} and write the result to \textit{outfile}. Only the non missing values of \textit{infile2} will be used. The horizontal grid of \textit{infile2} should be smaller or equal to the grid of \textit{infile1} and the resolution must be the same. Only rectilinear grids are supported. Both input files need to have the same variables and the same number of timesteps.
2.2.9. MERGE - Merge datasets

Synopsis

\[ <\text{operator}> \text{infiles} \text{outfile} \]

Description

This module reads datasets from several input files, merges them and writes the resulting dataset to \text{outfile}.

Operators

- **merge**
  Merge datasets with different fields
  Merges time series of different fields from several input datasets. The number of fields per timestep written to \text{outfile} is the sum of the field numbers per timestep in all input datasets. The time series on all input datasets are required to have different fields and the same number of timesteps. The fields in each different input file either have to be different variables or different levels of the same variable. A mixture of different variables on different levels in different input files is not allowed.

- **mergetime**
  Merge datasets sorted by date and time
  Merges all timesteps of all input files sorted by date and time. All input files need to have the same structure with the same variables on different timesteps. After this operation every input timestep is in \text{outfile} and all timesteps are sorted by date and time.

Environment

- **SKIP_SAME_TIME**
  If set to 1, skips all consecutive timesteps with a double entry of the same timestamp.

Note

Operators of this module need to open all input files simultaneously. The maximum number of open files depends on the operating system!

Example

Assume three datasets with the same number of timesteps and different variables in each dataset. To merge these datasets to a new dataset use:

```
cdo merge infile1 infile2 infile3 outfile
```

Assume you split a 6 hourly dataset with \text{splithour}. This produces four datasets, one for each hour. The following command merges them together:

```
cdo mergetime infile1 infile2 infile3 infile4 outfile
```
2.2.10. SPLIT - Split a dataset

Synopsis

<operator>[,params] infile obase

Description

This module splits infile into pieces. The output files will be named <obase><xxx><suffix> where suffix is the filename extension derived from the file format. xxx and the contents of the output files depend on the chosen operator. params is a comma-separated list of processing parameters.

Operators

- **splitcode**: Split code numbers
  Splits a dataset into pieces, one for each different code number. xxx will have three digits with the code number.

- **splitparam**: Split parameter identifiers
  Splits a dataset into pieces, one for each different parameter identifier. xxx will be a string with the parameter identifier.

- **splitname**: Split variable names
  Splits a dataset into pieces, one for each variable name. xxx will be a string with the variable name.

- **splitlevel**: Split levels
  Splits a dataset into pieces, one for each different level. xxx will have six digits with the level.

- **splitgrid**: Split grids
  Splits a dataset into pieces, one for each different grid. xxx will have two digits with the grid number.

- **splitzaxis**: Split z-axes
  Splits a dataset into pieces, one for each different z-axis. xxx will have two digits with the z-axis number.

- **splittabnum**: Split parameter table numbers
  Splits a dataset into pieces, one for each GRIB1 parameter table number. xxx will have three digits with the GRIB1 parameter table number.

Parameter

- **swap**: STRING
  Swap the position of obase and xxx in the output filename

- **uuid=<attname>**: STRING
  Add a UUID as global attribute <attname> to each output file

Environment

- **CDO_FILE_SUFFIX**: Set the default file suffix. This suffix will be added to the output file names instead of the filename extension derived from the file format. Set this variable to NULL to disable the adding of a file suffix.

Note

Operators of this module need to open all output files simultaneously. The maximum number of open files depends on the operating system!
Example

Assume an input GRIB1 dataset with three variables, e.g. code number 129, 130 and 139. To split this dataset into three pieces, one for each code number use:

```
cdo splitcode infile code
```

Result of `dir code*`:

```
code129.grb  code130.grb  code139.grb
```
2.2.11. SPLITTIME - Split timesteps of a dataset

Synopsis

\[ <operator> \text{ infile obase} \]

\[ \text{splitmon[,format]} \text{ infile obase} \]

Description

This module splits \text{infile} into timestep pieces. The output files will be named \(<\text{obase}><\text{xxx}><\text{suffix}>\) where \text{suffix} is the filename extension derived from the file format. \text{xxx} and the contents of the output files depends on the chosen operator.

Operators

- \text{splithour}  
  Split hours  
  Splits a file into pieces, one for each different hour. \text{xxx} will have two digits with the hour.

- \text{splitday}  
  Split days  
  Splits a file into pieces, one for each different day. \text{xxx} will have two digits with the day.

- \text{splitseas}  
  Split seasons  
  Splits a file into pieces, one for each different season. \text{xxx} will have three characters with the season.

- \text{splityear}  
  Split years  
  Splits a file into pieces, one for each different year. \text{xxx} will have four digits with the year (YYYY).

- \text{splityearmon}  
  Split in years and months  
  Splits a file into pieces, one for each different year and month. \text{xxx} will have six digits with the year and month (YYYYMM).

- \text{splitmon}  
  Split months  
  Splits a file into pieces, one for each different month. \text{xxx} will have two digits with the month.

Parameter

- \text{format}  
  \text{STRING}  
  C-style format for strftime() (e.g. %B for the full month name)

Environment

- \text{CDO_FILE_SUFFIX}  
  Set the default file suffix. This suffix will be added to the output file names instead of the filename extension derived from the file format. Set this variable to NULL to disable the adding of a file suffix.

Note

Operators of this module need to open all output files simultaneously. The maximum number of open files depends on the operating system!
Example

Assume the input GRIB1 dataset has timesteps from January to December. To split each month with all variables into one separate file use:

```
cdo splitmon infile mon
```

Result of 'dir mon*':

```
mon01.grib mon02.grib mon03.grib mon04.grib mon05.grib mon06.grib
mon07.grib mon08.grib mon09.grib mon10.grib mon11.grib mon12.grib
```

2.2.12. SPLITSEL - Split selected timesteps

Synopsis

```
splitsel, nsets[, noffset[, nskip]] infile obase
```

Description

This operator splits `infile` into pieces, one for each adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same selected time range. The output files will be named `<obase><nnn><suffix>` where `nnn` is the sequence number and `suffix` is the filename extension derived from the file format.

Parameter

- `nsets` INTEGER Number of input timesteps for each output file
- `noffset` INTEGER Number of input timesteps skipped before the first timestep range (optional)
- `nskip` INTEGER Number of input timesteps skipped between timestep ranges (optional)

Environment

- `CDO_FILE_SUFFIX` Set the default file suffix. This suffix will be added to the output file names instead of the filename extension derived from the file format. Set this variable to NULL to disable the adding of a file suffix.
2.2.13. DISTGRID - Distribute horizontal grid

Synopsis

distgrid, nx[, ny] infile obase

Description

This operator distributes a dataset into smaller pieces. Each output file contains a different region of the horizontal source grid. 2D Lon/Lat grids can be split into \( nx \times ny \) pieces, where a target grid region contains a structured longitude/latitude box of the source grid. Data on an unstructured grid is split into \( nx \) pieces. The output files will be named \(<obase><xxx><suffix>\) where suffix is the filename extension derived from the file format. \( xxx \) will have five digits with the number of the target region.

Parameter

- \( nx \) INTEGER Number of regions in x direction, or number of pieces for unstructured grids
- \( ny \) INTEGER Number of regions in y direction [default: 1]

Note

This operator needs to open all output files simultaneously. The maximum number of open files depends on the operating system!

Example

Distribute data on a 2D Lon/Lat grid into 6 smaller files, each output file receives one half of x and a third of y of the source grid:

```
cdo distgrid,2,3 infile.nc obase
```

Below is a schematic illustration of this example:

On the left side is the data of the input file and on the right side is the data of the six output files.
2.2.14. COLLGRID - Collect horizontal grid

Synopsis

\texttt{collgrid[,nx[,names]] infiles outfile}

Description

This operator collects the data of the input files to one output file. All input files need to have the same variables and the same number of timesteps on a different horizontal grid region. If the source regions are on a structured lon/lat grid, all regions together must result in a new structured lat/long grid box. Data on an unstructured grid is concatenated in the order of the input files. The parameter \texttt{nx} needs to be specified only for curvilinear grids.

Parameter

- \texttt{nx} INTEGER Number of regions in x direction [default: number of input files]
- \texttt{names} STRING Comma-separated list of variable names [default: all variables]

Note

This operator needs to open all input files simultaneously. The maximum number of open files depends on the operating system!

Example

Collect the horizontal grid of 6 input files. Each input file contains a lon/lat region of the target grid:

\texttt{cdo collgrid infile[1-6] outfile}

Below is a schematic illustration of this example:

On the left side is the data of the six input files and on the right side is the collected data of the output file.
2.3. Selection

This section contains modules to select time steps, fields or a part of a field from a dataset.

Here is a short overview of all operators in this section:

- **select**  Select fields
- **delete**  Delete fields
- **selmulti**  Select multiple fields
- **delmulti**  Delete multiple fields
- **changemulti**  Change identification of multiple fields
- **selparam**  Select parameters by identifier
- **delparam**  Delete parameters by identifier
- **selcode**  Select parameters by code number
- **delcode**  Delete parameters by code number
- **selname**  Select parameters by name
- **delname**  Delete parameters by name
- **selstdname**  Select parameters by standard name
- **sellevel**  Select levels
- **sellevidx**  Select levels by index
- **selgrid**  Select grids
- **selzaxis**  Select z-axes
- **selzaxisname**  Select z-axes by name
- **selltype**  Select GRIB level types
- **seltabnum**  Select parameter table numbers
- **seltimestep**  Select timesteps
- **seltime**  Select times
- **selhour**  Select hours
- **selday**  Select days
- **selmonth**  Select months
- **selyear**  Select years
- **selseason**  Select seasons
- **seldate**  Select dates
- **selsmon**  Select single month
- **sellonlatbox**  Select a longitude/latitude box
- **selindexbox**  Select an index box
- **selregion**  Select cells inside regions
- **selcircle**  Select cells inside a circle
- **selgridcell**  Select grid cells
- **delgridcell**  Delete grid cells
- **samplegrid**  Resample grid
- **selyearidx**  Select year by index
- **bottomvalue**  Extract bottom level
- **topvalue**  Extract top level
- **isosurface**  Extract isosurface
2.3.1. SELECT - Select fields

Synopsis

<operator>,params infiles outfile

Description

This module selects some fields from infiles and writes them to outfile. infiles is an arbitrary number of input files. All input files need to have the same structure with the same variables on different timesteps. The fields selected depends on the chosen parameters. Parameter is a comma-separated list of "key=value" pairs. A range of integer values can be specified by first/last[/inc]. Wildcards are supported for string values.

Operators

- **select**  
  Select fields  
  Selects all fields with parameters in a user given list.
- **delete**  
  Delete fields  
  Deletes all fields with parameters in a user given list.

Parameter

- **name** STRING  
  Comma-separated list of variable names.
- **param** STRING  
  Comma-separated list of parameter identifiers.
- **code** INTEGER  
  Comma-separated list or first/last[/inc] range of code numbers.
- **level** FLOAT  
  Comma-separated list of vertical levels.
- **levrange** FLOAT  
  First and last value of the level range.
- **zaxisidx** INTEGER  
  Comma-separated list or first/last[/inc] range of index of levels.
- **zaxisname** STRING  
  Comma-separated list of zaxis names.
- **zaxisnum** INTEGER  
  Comma-separated list or first/last[/inc] range of zaxis numbers.
- **ltype** INTEGER  
  Comma-separated list or first/last[/inc] range of GRIB level types.
- **gridname** STRING  
  Comma-separated list of grid names.
- **gridnum** INTEGER  
  Comma-separated list or first/last[/inc] range of grid numbers.
- **steptype** STRING  
  Comma-separated list of timestep types (constant, avg, accum, min, max, range, diff, sum)
- **date** STRING  
  Comma-separated list of dates (format YYYY-MM-DDThh:mm:ss).
- **startdate** STRING  
  Start date (format YYYY-MM-DDThh:mm:ss).
- **enddate** STRING  
  End date (format YYYY-MM-DDThh:mm:ss).
- **minute** INTEGER  
  Comma-separated list or first/last[/inc] range of minutes.
- **hour** INTEGER  
  Comma-separated list or first/last[/inc] range of hours.
- **day** INTEGER  
  Comma-separated list or first/last[/inc] range of days.
- **month** INTEGER  
  Comma-separated list or first/last[/inc] range of months.
- **season** STRING  
  Comma-separated list of seasons (substring of DJFMAMJJA-SOND or ANN).
Selection Reference manual

- **year**: INTEGER  Comma-separated list or first/last[/inc] range of years.
- **dom**: STRING  Comma-separated list of the day of month (e.g. 29feb).
- **timestep**: INTEGER  Comma-separated list or first/last[/inc] range of timesteps. Negative values select timesteps from the end (NetCDF only).
- **timestep_of_year**: INTEGER  Comma-separated list or first/last[/inc] range of timesteps of year.
- **timestepmask**: STRING  Read timesteps from a mask file.

### Example

Assume you have 3 input files. Each input file contains the same variables for a different time period. To select the variable T,U and V on the levels 200, 500 and 850 from all 3 input files, use:

```bash
  cdo select,name=T,U,V,level=200,500,850 infile1 infile2 infile3 outfile
```

To remove the February 29th use:

```bash
  cdo delete,dom=29feb infile outfile
```
### 2.3.2. SELMULTI - Select multiple fields via GRIB1 parameters

#### Synopsis

```
<operator>,selection-specification infile outfile
```

#### Description

This module selects multiple fields from `infile` and writes them to `outfile`. `selection-specification` is a filename or in-place string with the selection specification. Each `selection-specification` has the following compact notation format:

```
<type>(parameters; leveltype(s); levels)
```

- **type**: sel for select or del for delete (optional)
- **parameters**: GRIB1 parameter code number
- **leveltype**: GRIB1 level type
- **levels**: value of each level

**Examples:**

```
(1; 103; 0)
(33,34; 105; 10)
(11,17; 105; 2)
(71,73,74,75,61,62,65,117,67,122,121,11,131,66,84,111,112; 105; 0)
```

The following descriptive notation can also be used for selection specification from a file:

```
SELECT/DELETE, PARAMETER=parameters, LEVTYPE=leveltype(s), LEVEL=levels
```

**Examples:**

```
SELECT, PARAMETER=1, LEVTYPE=103, LEVEL=0
SELECT, PARAMETER=33/34, LEVTYPE=105, LEVEL=10
SELECT, PARAMETER=11/17, LEVTYPE=105, LEVEL=2
SELECT, PARAMETER=71/73/74/75/61/62/65/117/67/122, LEVTYPE=105, LEVEL=0
DELETE, PARAMETER=128, LEVTYPE=109, LEVEL=*  
```

The following will convert Pressure from Pa into hPa; Temp from Kelvin to Celsius:

```
SELECT, PARAMETER=1, LEVTYPE=103, LEVEL=0, SCALE=0.01
SELECT, PARAMETER=11, LEVTYPE=105, LEVEL=2, OFFSET=273.15
```

If `SCALE` and/or `OFFSET` are defined, then the data values are scaled as `SCALE*(VALUE-OFFSET)`.

#### Operators

- **selmulti**: Select multiple fields
- **delmulti**: Delete multiple fields
- **changemulti**: Change identification of multiple fields

#### Example

Change ECMWF GRIB code of surface pressure to Hirlam notation:

```
cdo changemulti,'{(134;1;*|1;105;*)}' infile outfile
```
2.3.3. SELVAR - Select fields

Synopsis

```
<operator>.params infile outfile
selcode,codes infile outfile
delcode,codes infile outfile
selname,names infile outfile

selstdname,stdnames infile outfile
sellevel,levels infile outfile
sellevidx,levidx infile outfile
selgrid,grids infile outfile
selzaxis,zaxes infile outfile
selzaxisname,zaxisnames infile outfile
selltype,ltypes infile outfile
seltabnum,tabnums infile outfile
```

Description

This module selects some fields from `infile` and writes them to `outfile`. The fields selected depend on the chosen operator and the parameters. A range of integer values can be specified by `first/last[/inc]`.

Operators

- **selparam**: Select parameters by identifier
  Selects all fields with parameter identifiers in a user given list.
- **delparam**: Delete parameters by identifier
  Deletes all fields with parameter identifiers in a user given list.
- **selcode**: Select parameters by code number
  Selects all fields with code numbers in a user given list or range.
- **delcode**: Delete parameters by code number
  Deletes all fields with code numbers in a user given list or range.
- **selname**: Select parameters by name
  Selects all fields with parameter names in a user given list.
- **delname**: Delete parameters by name
  Deletes all fields with parameter names in a user given list.
- **selstdname**: Select parameters by standard name
  Selects all fields with standard names in a user given list.
- **sellevel**: Select levels
  Selects all fields with standard names in a user given list.
- **sellevidx**: Select levels by index
  Selects all fields with index of levels in a user given list or range.
- **selgrid**: Select grids
  Selects all fields with grids in a user given list.
**Reference manual**

**Example**

Assume an input dataset has three variables with the code numbers 129, 130 and 139. To select the variables with the code number 129 and 139 use:

```
cdo selcode,129,139 infile outfile
```

You can also select the code number 129 and 139 by deleting the code number 130 with:

```
cdo delcode,130 infile outfile
```
2.3.4. SELTIME - Select timesteps

Synopsis

\begin{verbatim}
sel timestep, timesteps  infile outfile
sel time, times  infile outfile
sel hour, hours  infile outfile
sel day, days  infile outfile
sel month, months  infile outfile
sel year, years  infile outfile
sel season, seasons  infile outfile
sel date, startdate[,enddate]  infile outfile
sel mon, month[,nts1[,nts2]]  infile outfile
\end{verbatim}

Description

This module selects user specified timesteps from infile and writes them to outfile. The timesteps selected depends on the chosen operator and the parameters. A range of integer values can be specified by first/last/\textit{inc}.

Operators

\begin{verbatim}
sel timestep  Select timesteps
  Selects all timesteps with a timestep in a user given list or range.
sel time  Select times
  Selects all timesteps with a time in a user given list or range.
sel hour  Select hours
  Selects all timesteps with a hour in a user given list or range.
sel day  Select days
  Selects all timesteps with a day in a user given list or range.
sel month  Select months
  Selects all timesteps with a month in a user given list or range.
sel year  Select years
  Selects all timesteps with a year in a user given list or range.
sel season  Select seasons
  Selects all timesteps with a month of a season in a user given list.
sel date  Select dates
  Selects all timesteps with a date in a user given range.
sel mon  Select single month
  Selects a month and optional an arbitrary number of timesteps before and after this month.
\end{verbatim}
Parameter

<table>

</tbody>
</table>
2.3.5. SELBOX - Select a box

Synopsis

sellonlatbox,lon1,lon2,lat1,lat2  infile  outfile
selindexbox,idx1,idx2,idy1,idy2  infile  outfile

Description

Selects grid cells inside a lon/lat or index box.

Operators

sellonlatbox  Select a longitude/latitude box
Selects grid cells inside a lon/lat box. The user must specify the longitude and
latitude of the edges of the box. Only those grid cells are considered whose grid
center lies within the lon/lat box. For rotated lon/lat grids the parameters must
be specified in rotated coordinates.

selindexbox  Select an index box
Selects grid cells within an index box. The user must specify the indices of the
edges of the box. The index of the left edge can be greater than the one of the
right edge. Use negative indexing to start from the end. The input grid must be a
regular lon/lat or a 2D curvilinear grid.

Parameter

lon1  FLOAT  Western longitude in degrees
lon2  FLOAT  Eastern longitude in degrees
lat1  FLOAT  Southern or northern latitude in degrees
lat2  FLOAT  Northern or southern latitude in degrees
idx1  INTEGER  Index of first longitude (1 - nlon)
idx2  INTEGER  Index of last longitude (1 - nlon)
idy1  INTEGER  Index of first latitude (1 - nlat)
idy2  INTEGER  Index of last latitude (1 - nlat)

Example

To select the region with the longitudes from 30W to 60E and latitudes from 30N to 80N from all
input fields use:

```
cdo sellonlatbox,-30,60,30,80 infile outfile
```

If the input dataset has fields on a Gaussian N16 grid, the same box can be selected with selindexbox
by:

```
cdo selindexbox,60,11,3,11 infile outfile
```
2.3.6. SELREGION - Select horizontal regions

Synopsis

selregion,regions infile outfile
selcircle[,lon,lat,radius] infile outfile

Description

Selects all grid cells with the center point inside user defined regions or a circle. The resulting grid is unstructured.

Operators

selregion Select cells inside regions
Selects all grid cells with the center point inside the regions. The user has to give ASCII formatted files with different regions. A region is defined by a polygon. Each line of a polygon description file contains the longitude and latitude of one point. Each polygon description file can contain one or more polygons separated by a line with the character &.

selcircle Select cells inside a circle
Selects all grid cells with the center point inside a circle. The circle is described by geographic coordinates of the center and the radius of the circle.

Parameter

regions STRING Comma-separated list of ASCII formatted files with different regions
lon FLOAT Longitude of the center of the circle in degrees, default lon=0.0
lat FLOAT Latitude of the center of the circle in degrees, default lat=0.0
radius STRING Radius of the circle, default radius=1deg (units: deg, rad, km, m)
2.3.7. SELGRIDCELL - Select grid cells

Synopsis

<operator>,indices infile outfile

Description

The operator selects grid cells of all fields from infile. The user must specify the index of each grid cell. The resulting grid in outfile is unstructured.

Operators

- selgridcell: Select grid cells
- delgridcell: Delete grid cells

Parameter

indices INTEGER Comma-separated list or first/last/[inc] range of indices

2.3.8. SAMPLEGRID - Resample grid

Synopsis

samplegrid.factor infile outfile

Description

This is a special operator for resampling the horizontal grid. No interpolation takes place. Resample factor=2 means every second grid point is removed. Only rectilinear and curvilinear source grids are supported by this operator.

Parameter

factor INTEGER Resample factor, typically 2, which will half the resolution

2.3.9. SELYEARIDX - Select year by index

Synopsis

selyearidx infile1 infile2 outfile

Description

Selects field elements from infile2 by a yearly time index from infile1. The yearly indices in infile1 should be the result of corresponding yearminidx and yearmaxidx operations, respectively.
2.3.10. SELSURFACE - Extract surface

Synopsis

<operator> infile outfile

isosurface, isovalue infile outfile

Description

This module computes a surface from all 3D variables. The result is a horizontal 2D field.

Operators

bottomvalue
Extract bottom level
This operator selects the valid values at the bottom level. The NetCDF CF compliant attribute positive is used to determine where top and bottom are. If this attribute is missing, low values are bottom and high values are top.

topvalue
Extract top level
This operator selects the valid values at the top level. The NetCDF CF compliant attribute positive is used to determine where top and bottom are. If this attribute is missing, low values are bottom and high values are top.

isosurface
Extract isosurface
This operator computes an isosurface. The value of the isosurface is specified by the parameter isovalue. The isosurface is calculated by linear interpolation between two layers.

Parameter

isovalue FLOAT Isosurface value
2.4. Conditional selection

This section contains modules to conditional select field elements. The fields in the first input file are handled as a mask. A value not equal to zero is treated as 'true', zero is treated as 'false'.

Here is a short overview of all operators in this section:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ifthen</td>
<td>If then</td>
</tr>
<tr>
<td>ifnotthen</td>
<td>If not then</td>
</tr>
<tr>
<td>ifthenelse</td>
<td>If then else</td>
</tr>
<tr>
<td>ifthenc</td>
<td>If then constant</td>
</tr>
<tr>
<td>ifnotthenc</td>
<td>If not then constant</td>
</tr>
<tr>
<td>reducegrid</td>
<td>Reduce input file variables to locations, where mask is non-zero.</td>
</tr>
</tbody>
</table>
2.4.1. COND - Conditional select one field

Synopsis

\( <\text{operator}> \) infile1 infile2 outfile

Description

This module selects field elements from infile2 with respect to infile1 and writes them to outfile. The fields in infile1 are handled as a mask. A value not equal to zero is treated as 'true', zero is treated as 'false'. The number of fields in infile1 has either to be the same as in infile2 or the same as in one timestep of infile2 or only one. The fields in outfile inherit the meta data from infile2.

Operators

ifthen

\[ o(t,x) = \begin{cases} i_2(t,x) & \text{if } i_1([t,x]) \neq 0 \land i_1([t,x]) \neq \text{miss} \\ \text{miss} & \text{if } i_1([t,x]) = 0 \lor i_1([t,x]) = \text{miss} \end{cases} \]

ifnotthen

\[ o(t,x) = \begin{cases} i_2(t,x) & \text{if } i_1([t,x]) = 0 \land i_1([t,x]) \neq \text{miss} \\ \text{miss} & \text{if } i_1([t,x]) \neq 0 \lor i_1([t,x]) = \text{miss} \end{cases} \]

Example

To select all field elements of infile2 if the corresponding field element of infile1 is greater than 0 use:

\[
\text{cdo ifthen infile1 infile2 outfile}
\]

2.4.2. COND2 - Conditional select two fields

Synopsis

ifthenelse infile1 infile2 infile3 outfile

Description

This operator selects field elements from infile2 or infile3 with respect to infile1 and writes them to outfile. The fields in infile1 are handled as a mask. A value not equal to zero is treated as 'true', zero is treated as 'false'. The number of fields in infile1 has either to be the same as in infile2 or the same as in one timestep of infile2 or only one. infile2 and infile3 need to have the same number of fields. The fields in outfile inherit the meta data from infile2.

\[ o(t,x) = \begin{cases} i_2(t,x) & \text{if } i_1([t,x]) \neq 0 \land i_1([t,x]) \neq \text{miss} \\
  i_3(t,x) & \text{if } i_1([t,x]) = 0 \land i_1([t,x]) \neq \text{miss} \\
  \text{miss} & \text{if } i_1([t,x]) = \text{miss} \end{cases} \]

Example

To select all field elements of infile2 if the corresponding field element of infile1 is greater than 0 and from infile3 otherwise use:

\[
\text{cdo ifthenelse infile1 infile2 infile3 outfile}
\]
2.4.3. CONDC - Conditional select a constant

Synopsis

<operator>,c infile outfile

Description

This module creates fields with a constant value or missing value. The fields in infile are handled as a mask. A value not equal to zero is treated as "true", zero is treated as "false".

Operators

\[
\text{ifthen} \quad o(t,x) = \begin{cases} 
  c & \text{if } i(t,x) \neq 0 \land i(t,x) \neq \text{miss} \\
  \text{miss} & \text{if } i(t,x) = 0 \lor i(t,x) = \text{miss}
\end{cases}
\]

\[
\text{ifnotthen} \quad o(t,x) = \begin{cases} 
  c & \text{if } i(t,x) = 0 \land i(t,x) \neq \text{miss} \\
  \text{miss} & \text{if } i(t,x) \neq 0 \lor i(t,x) = \text{miss}
\end{cases}
\]

Parameter

\[
c \quad \text{FLOAT} \quad \text{Constant}
\]

Example

To create fields with the constant value 7 if the corresponding field element of infile is greater than 0 use:

\[
\text{cdo ifthen}c,7 \text{ infile outfile}
\]
2.4.4. MAPREDUCE - Reduce fields to user-defined mask

Synopsis

`reducegrid,mask[,limitCoordsOutput]` `infile outfile`

Description

This module holds an operator for data reduction based on a user defined mask. The output grid is unstructured and includes coordinate bounds. Bounds can be avoided by using the additional 'nobounds' keyword. With 'nocoords' given, coordinates are completely suppressed.

Parameter

- `mask` STRING file which holds the mask field
- `limitCoordsOutput` STRING optional parameter to limit coordinates output: 'nobounds' disables coordinate bounds, 'nocoords' avoids all coordinate information

Example

To limit data fields to land values, a mask has to be created first with

```
cdo -gtc,0 -topo,ni96 lsm_gme96.grb
```

Here a GME grid is used. Say temp_gme96.grb contains a global temperature field. The following command limits the global grid to landpoints.

```
cdo -f nc reduce,lsm_gme96.grb temp_gme96.grb tempOnLand_gme96.nc
```

Note that output file type is NetCDF, because unstructured grids cannot be stored in GRIB format.
2.5. Comparison

This section contains modules to compare datasets. The resulting field is a mask containing 1 if the comparison is true and 0 if not.

Here is a short overview of all operators in this section:

<table>
<thead>
<tr>

</tr>
<tr>
<td>gec</td>
<td>Greater equal constant</td>
</tr>
<tr>
<td>gtc</td>
<td>Greater than constant</td>
</tr>
</tbody>
</table>
2.5.1. COMP - Comparison of two fields

Synopsis

\[ \texttt{<operator>} \texttt{in} \texttt{file1} \texttt{in} \texttt{file2} \texttt{outfile} \]

Description

This module compares two datasets field by field. The resulting field is a mask containing 1 if the comparison is true and 0 if not. The number of fields in \texttt{in} \texttt{file1} should be the same as in \texttt{in} \texttt{file2}. One of the input files can contain only one timestep or one field. The fields in \texttt{outfile} inherit the meta data from \texttt{in} \texttt{file1} or \texttt{in} \texttt{file2}. The type of comparison depends on the chosen operator.

Operators

\[ o(t,x) = \begin{cases} 1 & \text{if } i_1(t,x) = i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ 0 & \text{if } i_1(t,x) \neq i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ \text{miss} & \text{if } i_1(t,x) = \text{miss} \lor i_2(t,x) = \text{miss} \end{cases} \]

\[ o(t,x) = \begin{cases} 1 & \text{if } i_1(t,x) \neq i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ 0 & \text{if } i_1(t,x) = i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ \text{miss} & \text{if } i_1(t,x) = \text{miss} \lor i_2(t,x) = \text{miss} \end{cases} \]

\[ o(t,x) = \begin{cases} 1 & \text{if } i_1(t,x) \leq i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ 0 & \text{if } i_1(t,x) > i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ \text{miss} & \text{if } i_1(t,x) = \text{miss} \lor i_2(t,x) = \text{miss} \end{cases} \]

\[ o(t,x) = \begin{cases} 1 & \text{if } i_1(t,x) < i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ 0 & \text{if } i_1(t,x) \geq i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ \text{miss} & \text{if } i_1(t,x) = \text{miss} \lor i_2(t,x) = \text{miss} \end{cases} \]

\[ o(t,x) = \begin{cases} 1 & \text{if } i_1(t,x) \geq i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ 0 & \text{if } i_1(t,x) < i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ \text{miss} & \text{if } i_1(t,x) = \text{miss} \lor i_2(t,x) = \text{miss} \end{cases} \]

\[ o(t,x) = \begin{cases} 1 & \text{if } i_1(t,x) > i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ 0 & \text{if } i_1(t,x) \leq i_2(t,x) \land i_1(t,x),i_2(t,x) \neq \text{miss} \\ \text{miss} & \text{if } i_1(t,x) = \text{miss} \lor i_2(t,x) = \text{miss} \end{cases} \]

Example

To create a mask containing 1 if the elements of two fields are the same and 0 if the elements are different use:

\[ \texttt{cdo eq infile1 infile2 outfile} \]
2.5.2. COMPC - Comparison of a field with a constant

Synopsis

\(<\text{operator}>, c \text{ infile outfile}\>

Description

This module compares all fields of a dataset with a constant. The resulting field is a mask containing 1 if the comparison is true and 0 if not. The type of comparison depends on the chosen operator.

Operators

- **eqc** Equal constant
  
  \[
  o(t, x) = \begin{cases} 
  1 & \text{if } i(t, x) = c \land i(t, x), c \neq \text{miss} \\
  0 & \text{if } i(t, x) \neq c \land i(t, x), c \neq \text{miss} \\
  \text{miss} & \text{if } i(t, x) = \text{miss} \lor c = \text{miss}
  \end{cases}
  \]

- **nec** Not equal constant
  
  \[
  o(t, x) = \begin{cases} 
  1 & \text{if } i(t, x) \neq c \land i(t, x), c \neq \text{miss} \\
  0 & \text{if } i(t, x) = c \land i(t, x), c \neq \text{miss} \\
  \text{miss} & \text{if } i(t, x) = \text{miss} \lor c = \text{miss}
  \end{cases}
  \]

- **lec** Less equal constant
  
  \[
  o(t, x) = \begin{cases} 
  1 & \text{if } i(t, x) \leq c \land i(t, x), c \neq \text{miss} \\
  0 & \text{if } i(t, x) > c \land i(t, x), c \neq \text{miss} \\
  \text{miss} & \text{if } i(t, x) = \text{miss} \lor c = \text{miss}
  \end{cases}
  \]

- **ltc** Less than constant
  
  \[
  o(t, x) = \begin{cases} 
  1 & \text{if } i(t, x) < c \land i(t, x), c \neq \text{miss} \\
  0 & \text{if } i(t, x) \geq c \land i(t, x), c \neq \text{miss} \\
  \text{miss} & \text{if } i(t, x) = \text{miss} \lor c = \text{miss}
  \end{cases}
  \]

- **gec** Greater equal constant
  
  \[
  o(t, x) = \begin{cases} 
  1 & \text{if } i(t, x) \geq c \land i(t, x), c \neq \text{miss} \\
  0 & \text{if } i(t, x) < c \land i(t, x), c \neq \text{miss} \\
  \text{miss} & \text{if } i(t, x) = \text{miss} \lor c = \text{miss}
  \end{cases}
  \]

- **gtc** Greater than constant
  
  \[
  o(t, x) = \begin{cases} 
  1 & \text{if } i(t, x) > c \land i(t, x), c \neq \text{miss} \\
  0 & \text{if } i(t, x) \leq c \land i(t, x), c \neq \text{miss} \\
  \text{miss} & \text{if } i(t, x) = \text{miss} \lor c = \text{miss}
  \end{cases}
  \]

Parameter

- **c** FLOAT Constant

Example

To create a mask containing 1 if the field element is greater than 273.15 and 0 if not use:

```
cdo gtc,273.15 infile outfile
```
2.6. Modification

This section contains modules to modify the metadata, fields or part of a field in a dataset.

Here is a short overview of all operators in this section:

- **setattribute**: Set attributes
- **setpartabp**: Set parameter table
- **setpartabn**: Set parameter table
- **setcodetab**: Set parameter code table
- **setcode**: Set code number
- **setparam**: Set parameter identifier
- **setname**: Set variable name
- **setunit**: Set variable unit
- **setlevel**: Set level
- **setltype**: Set GRIB level type
- **setdate**: Set date
- **settime**: Set time of the day
- **setday**: Set day
- **setmon**: Set month
- **setyear**: Set year
- **settunits**: Set time units
- **settaxis**: Set time axis
- **settbounds**: Set time bounds
- **setreftime**: Set reference time
- **setcalendar**: Set calendar
- **shifttime**: Shift timesteps
- **chcode**: Change code number
- **chparam**: Change parameter identifier
- **chname**: Change variable or coordinate name
- **chunit**: Change variable unit
- **chlevel**: Change level
- **chlevelc**: Change level of one code
- **chlevelv**: Change level of one variable
- **setgrid**: Set grid
- **setgridtype**: Set grid type
- **setgridarea**: Set grid cell area
- **setgridmask**: Set grid mask
- **setzaxis**: Set z-axis
- **genlevelbounds**: Generate level bounds
- **invertlat**: Invert latitudes
- **inverterlev**: Invert levels
- **shiftx**: Shift x
- **shifty**: Shift y
- **maskregion**: Mask regions

<td><code>setgridcell</code></td>
<td>Set the value of a grid cell</td>
</tr>
</tbody>
</table>
2.6.1. SETATTRIBUTE - Set attributes

Synopsis

```
setattribute,attributes infile outfile
```

Description

This operator sets attributes of a dataset and writes the result to outfile. The new attributes are only available in outfile if the file format supports attributes.

Each attribute has the following structure:

```
[var_nmm@]att_nnm[is]i=att_val{[var_nnm@]att_nnm]
```

- **var_nnm**: Variable name (optional). Example: pressure
- **att_nnm**: Attribute name. Example: units
- **att_val**: Comma-separated list of attribute values. Example: pascal

The value of **var_nnm** is the name of the variable containing the attribute (named **att_nnm**) that you want to set. Use wildcards to set the attribute **att_nnm** to more than one variable. A value of **var_nnm** of `*` will set the attribute **att_nnm** to all data variables. If **var_nnm** is missing then **att_nnm** refers to a global attribute.

The value of **att_nnm** is the name of the attribute you want to set. For each attribute a string (**att_nnm**:s), a double (**att_nnm**:d) or an integer (**att_nnm**:i) type can be defined. By default the native type is set.

The value of **att_val** is the contents of the attribute **att_nnm**. **att_val** may be a single value or one-dimensional array of elements. The type and the number of elements of an attribute will be detected automatically from the contents of the values. An already existing attribute **att_nnm** will be overwritten or it will be removed if **att_val** is omitted. Alternatively, the values of an existing attribute can be copied. This attribute must then be enclosed in curly brackets.

A special meaning has the attribute name **FILE**. If this is the 1st attribute then all attributes are read from a file specified in the value of **att_val**.

Parameter

```
 attributes STRING Comma-separated list of attributes.
```

Note

Attributes are evaluated by **CDO** when opening **infile**. Therefor the result of this operator is not available for other operators when this operator is used in chaining operators.

Example

To set the units of the variable pressure to pascal use:

```
cdo setattribute,pressure@units=pascal infile outfile
```

To set the global text attribute 'my_att' to 'my contents', use:

```
cdo setattribute,my_att="my contents" infile outfile
```

Result of `ncdump -h outfile':

```
71
```
netcdf outfile {
dimensions: ...

variables: ...

// global attributes:
    :my_att = 'my contents' ;
}

2.6.2. SETPARTAB - Set parameter table

Synopsis

\(<\text{operator}>\), table[,convert] infile outfile

Description

This module transforms data and metadata of infile via a parameter table and writes the result to outfile. A parameter table is an ASCII formatted file with a set of parameter entries for each variable. Each new set have to start with "&parameter" and to end with "/".

The following parameter table entries are supported:

<table>
<thead>
<tr>
<th>Entry</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>WORD</td>
<td>Name of the variable</td>
</tr>
<tr>
<td>out_name</td>
<td>WORD</td>
<td>New name of the variable</td>
</tr>
<tr>
<td>param</td>
<td>WORD</td>
<td>Parameter identifier (GRIB1: code[.tabnum]; GRIB2: num[.cat[.dis]])</td>
</tr>
<tr>
<td>out_param</td>
<td>WORD</td>
<td>New parameter identifier</td>
</tr>
<tr>
<td>type</td>
<td>WORD</td>
<td>Data type (real or double)</td>
</tr>
<tr>
<td>standard_name</td>
<td>WORD</td>
<td>As defined in the CF standard name table</td>
</tr>
<tr>
<td>long_name</td>
<td>STRING</td>
<td>Describing the variable</td>
</tr>
<tr>
<td>units</td>
<td>STRING</td>
<td>Specifying the units for the variable</td>
</tr>
<tr>
<td>comment</td>
<td>STRING</td>
<td>Information concerning the variable</td>
</tr>
<tr>
<td>cell_methods</td>
<td>STRING</td>
<td>Information concerning calculation of means or climatologies</td>
</tr>
<tr>
<td>cell_measures</td>
<td>STRING</td>
<td>Indicates the names of the variables containing cell areas and volumes</td>
</tr>
<tr>
<td>missing_value</td>
<td>FLOAT</td>
<td>Specifying how missing data will be identified</td>
</tr>
<tr>
<td>valid_min</td>
<td>FLOAT</td>
<td>Minimum valid value</td>
</tr>
<tr>
<td>valid_max</td>
<td>FLOAT</td>
<td>Maximum valid value</td>
</tr>
<tr>
<td>ok_min_mean_abs</td>
<td>FLOAT</td>
<td>Minimum absolute mean</td>
</tr>
<tr>
<td>ok_max_mean_abs</td>
<td>FLOAT</td>
<td>Maximum absolute mean</td>
</tr>
<tr>
<td>factor</td>
<td>FLOAT</td>
<td>Scale factor</td>
</tr>
<tr>
<td>delete</td>
<td>INTEGER</td>
<td>Set to 1 to delete variable</td>
</tr>
<tr>
<td>convert</td>
<td>INTEGER</td>
<td>Set to 1 to convert the unit if necessary</td>
</tr>
</tbody>
</table>

Unsupported parameter table entries are stored as variable attributes. The search key for the variable depends on the operator. Use setpartabn to search variables by the name. This is typically used for NetCDF datasets. The operator setpartabp searches variables by the parameter ID.

Operators

setpartabp  Set parameter table
Search variables by the parameter identifier.

setpartabn  Set parameter table
Search variables by name.

Parameter

| table       | STRING | Parameter table file or name                                     |
| convert     | STRING | Converts the units if necessary                                 |
Example

Here is an example of a parameter table for one variable:

```
prompt> cat mypartab
&parameter
  name = t
  out_name = ta
  standard_name = air_temperature
  units = "K"
  missing_value = 1.0e+20
  valid_min = 157.1
  valid_max = 336.3
/
```

To apply this parameter table to a dataset use:

```
cdo setpartabn,mypartab,convert infile outfile
```

This command renames the variable t to ta. The standard name of this variable is set to `air_temperature` and the unit is set to [K] (converts the unit if necessary). The missing value will be set to 1.0e+20. In addition it will be checked whether the values of the variable are in the range of 157.1 to 336.3.
2.6.3. SET - Set field info

Synopsis

```plaintext
setcodetab, table  infile outfile
setcode, code  infile outfile
setparam, param  infile outfile
setname, name  infile outfile
setunit, unit  infile outfile
setlevel, level  infile outfile
setltype, ltype  infile outfile
```

Description

This module sets some field information. Depending on the chosen operator the parameter table, code number, parameter identifier, variable name or level is set.

Operators

```plaintext
setcodetab  Set parameter code table
            Sets the parameter code table for all variables.
setcode  Set code number
            Sets the code number for all variables to the same given value.
setparam  Set parameter identifier
            Sets the parameter identifier of the first variable.
setname  Set variable name
            Sets the name of the first variable.
setunit  Set variable unit
            Sets the unit of the first variable.
setlevel  Set level
            Sets the first level of all variables.
setltype  Set GRIB level type
            Sets the GRIB level type of all variables.
```

Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>STRING</td>
<td>Parameter table file or name</td>
</tr>
<tr>
<td>code</td>
<td>INTEGER</td>
<td>Code number</td>
</tr>
<tr>
<td>param</td>
<td>STRING</td>
<td>Parameter identifier (GRIB1: code[.tabnum]; GRIB2: num[.cat[.dis]])</td>
</tr>
<tr>
<td>name</td>
<td>STRING</td>
<td>Variable name</td>
</tr>
<tr>
<td>level</td>
<td>FLOAT</td>
<td>New level</td>
</tr>
<tr>
<td>ltype</td>
<td>INTEGER</td>
<td>GRIB level type</td>
</tr>
</tbody>
</table>
2.6.4. SETTIME - Set time

Synopsis

```plaintext
setdate, date infile outfile
settime, time infile outfile
setday, day infile outfile
setmon, month infile outfile
setyear, year infile outfile
settunits, units infile outfile
settaxis, units, time, date[,inc] infile outfile
settbounds, frequency infile outfile
setreftime, date, time[,units] infile outfile
setcalendar, calendar infile outfile
shifttime, sval infile outfile
```

Description

This module sets the time axis or part of the time axis. Which part of the time axis is overwritten/created depends on the chosen operator.

Operators

- setdate: Set date
  - Sets the date in every timestep to the same given value.
- settime: Set time of the day
  - Sets the time in every timestep to the same given value.
- setday: Set day
  - Sets the day in every timestep to the same given value.
- setmon: Set month
  - Sets the month in every timestep to the same given value.
- setyear: Set year
  - Sets the year in every timestep to the same given value.
- settunits: Set time units
  - Sets the base units of a relative time axis.
- settaxis: Set time axis
  - Sets the time axis.
- settbounds: Set time bounds
  - Sets the time bounds.
- setreftime: Set reference time
  - Sets the reference time of a relative time axis.
- setcalendar: Set calendar
  - Sets the calendar of a relative time axis.
- shifttime: Shift timesteps
  - Shifts all timesteps by the parameter sval.
Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>day</td>
<td>INTEGER</td>
<td>Value of the new day</td>
</tr>
<tr>
<td>month</td>
<td>INTEGER</td>
<td>Value of the new month</td>
</tr>
<tr>
<td>year</td>
<td>INTEGER</td>
<td>Value of the new year</td>
</tr>
<tr>
<td>units</td>
<td>STRING</td>
<td>Base units of the time axis (seconds, minutes, hours, days, months, years)</td>
</tr>
<tr>
<td>date</td>
<td>STRING</td>
<td>Date (format: YYYY-MM-DD)</td>
</tr>
<tr>
<td>time</td>
<td>STRING</td>
<td>Time (format: hh:mm:ss)</td>
</tr>
<tr>
<td>inc</td>
<td>STRING</td>
<td>Optional increment (seconds, minutes, hours, days, months, years) [default: 1hour]</td>
</tr>
<tr>
<td>frequency</td>
<td>STRING</td>
<td>Frequency of the time series (hour, day, month, year)</td>
</tr>
<tr>
<td>calendar</td>
<td>STRING</td>
<td>Calendar (standard, proleptic_gregorian, 360_day, 365_day, 366_day)</td>
</tr>
<tr>
<td>sval</td>
<td>STRING</td>
<td>Shift value (e.g. -3hour)</td>
</tr>
</tbody>
</table>

Example

To set the time axis to 1987-01-16 12:00:00 with an increment of one month for each timestep use:

```
cdo settaxis,1987-01-16,12:00:00,1mon infile outfile
```

Result of `cdo showdate outfile` for a dataset with 12 timesteps:

```
```

To shift this time axis by -15 days use:

```
cdo shifttime,-15days infile outfile
```

Result of `cdo showdate outfile`:

```
1987−01−01 1987−02−01 1987−03−01 1987−04−01 1987−05−01 1987−06−01 1987−07−01 1987−08−01 1987−09−01 1987−10−01 1987−11−01 1987−12−01
```
2.6.5. CHANGE - Change field header

Synopsis

chcode,oldcode,newcode[,...]  infile outfile  
chparam,oldparam,newparam,...  infile outfile  
chname,oldname,newname,...  infile outfile  
chunit,oldunit,newunit,...  infile outfile  
chlevel,oldlev,newlev,...  infile outfile  
chlevelc,code,oldlev,newlev  infile outfile  
chlevelv,name,oldlev,newlev  infile outfile  

Description

This module reads fields from infile, changes some header values and writes the results to outfile. The kind of changes depends on the chosen operator.

Operators

chcode  Change code number
Changes some user given code numbers to new user given values.

chparam  Change parameter identifier
Changes some user given parameter identifiers to new user given values.

chname  Change variable or coordinate name
Changes some user given variable or coordinate names to new user given names.

chunit  Change variable unit
Changes some user given variable units to new user given units.

chlevel  Change level
Changes some user given levels to new user given values.

chlevelc  Change level of one code
Changes one level of a user given code number.

chlevelv  Change level of one variable
Changes one level of a user given variable name.

Parameter

code INTEGER Code number
oldcode,newcode,... INTEGER Pairs of old and new code numbers
oldparam,newparam,... STRING Pairs of old and new parameter identifiers
name STRING Variable name
oldname,newname,... STRING Pairs of old and new variable names
oldlev FLOAT Old level
newlev FLOAT New level
oldlev,newlev,... FLOAT Pairs of old and new levels

Example

To change the code number 98 to 179 and 99 to 211 use:

cdo chcode,98,179,99,211 infile outfile
2.6.6. SETGRID - Set grid information

Synopsis

setgrid,grid infile outfile
setgridtype,gridtype infile outfile
setgridarea,gridarea infile outfile
setgridmask,gridmask infile outfile

Description

This module modifies the metadata of the horizontal grid. Depending on the chosen operator a new
grid description is set, the coordinates are converted or the grid cell area is added.

Operators

setgrid  Set grid
Sets a new grid description. The input fields need to have the same grid size as the
size of the target grid description.

setgridtype  Set grid type
Sets the grid type of all input fields. The following grid types are available:
curvilinear  Converts a regular grid to a curvilinear grid
unstructured  Converts a regular or curvilinear grid to an unstructured grid
dereference  Dereference a reference to a grid
regular  Linear interpolation of a reduced Gaussian grid to a regular Gaussian grid
regularnn  Nearest neighbor interpolation of a reduced Gaussian grid to a
regular Gaussian grid
lonlat  Converts a regular lonlat grid stored as a curvilinear grid back to
a lonlat grid

setgridarea  Set grid cell area
Sets the grid cell area. The parameter gridarea is the path to a data file, the first
field is used as grid cell area. The input fields need to have the same grid size as the
grid cell area. The grid cell area is used to compute the weights of each grid cell if
needed by an operator, e.g. for fldmean.

setgridmask  Set grid mask
Sets the grid mask. The parameter gridmask is the path to a data file, the first field
is used as the grid mask. The input fields need to have the same grid size as the
grid mask. The grid mask is used as the target grid mask for remapping, e.g. for
remapbil.

Parameter

grid  STRING  Grid description file or name
gridtype  STRING  Grid type (curvilinear, unstructured, regular, lonlat or dereference)
gridarea  STRING  Data file, the first field is used as grid cell area
gridmask  STRING  Data file, the first field is used as grid mask
Example

Assuming a dataset has fields on a grid with 2048 elements without or with wrong grid description. To set the grid description of all input fields to a Gaussian N32 grid (8192 gridpoints) use:

```
cdo setgrid,n32 infile outfile
```

2.6.7. SETZAXIS - Set z-axis information

Synopsis

```
setzaxis,zaxis infile outfile

genlevelbounds[,zbot[,ztop]] infile outfile
```

Description

This module modifies the metadata of the vertical grid.

Operators

- **setzaxis**
  - Set z-axis
  - This operator sets the z-axis description of all variables with the same number of level as the new z-axis.

- **genlevelbounds**
  - Generate level bounds
  - Generates the layer bounds of the z-axis.

Parameter

- **zaxis** STRING
  - Z-axis description file or name of the target z-axis

- **zbot** FLOAT
  - Specifying the bottom of the vertical column. Must have the same units as z-axis.

- **ztop** FLOAT
  - Specifying the top of the vertical column. Must have the same units as z-axis.
2.6.8. INVERT - Invert latitudes

Synopsis

invertlat infile outfile

Description

This operator inverts the latitudes of all fields on a rectilinear grid.

Example

To invert the latitudes of a 2D field from N->S to S->N use:

```
cdo invertlat infile outfile
```

2.6.9. INVERTLEV - Invert levels

Synopsis

invertlev infile outfile

Description

This operator inverts the levels of all 3D variables.
2.6.10. SHIFTXY - Shift field

Synopsis

<operator>,<nshift>,<cyclic>,<coord> infile outfile

Description

This module contains operators to shift all fields in x or y direction. All fields need to have the same horizontal rectilinear or curvilinear grid.

Operators

shiftx  Shift x
Shifts all fields in x direction.

shifty  Shift y
Shifts all fields in y direction.

Parameter

nshift  INTEGER  Number of grid cells to shift (default: 1)
cyclic  STRING  If set, cells are filled up cyclic (default: missing value)
coord   STRING   If set, coordinates are also shifted

Example

To shift all input fields in the x direction by +1 cells and fill the new cells with missing value, use:

```
cdo shiftx infile outfile
```

To shift all input fields in the x direction by +1 cells and fill the new cells cyclic, use:

```
cdo shiftx,1,cyclic infile outfile
```
2.6.11. MASKREGION - Mask regions

Synopsis

\texttt{maskregion,regions infile outfile}

Description

Masks different regions of fields with a regular lon/lat grid. The elements inside a region are untouched, the elements outside are set to missing value. Considered are only those grid cells with the grid center inside the regions. All input fields must have the same horizontal grid. The user has to give ASCII formatted files with different regions. A region is defined by a polygon. Each line of a polygon description file contains the longitude and latitude of one point. Each polygon description file can contain one or more polygons separated by a line with the character \\

Parameter

regions \hspace{1cm} \text{STRING} \hspace{1cm} \text{Comma-separated list of ASCII formatted files with different regions}

Example

To mask the region with the longitudes from 120E to 90W and latitudes from 20N to 20S on all input fields use:

\texttt{cdo maskregion,myregion infile outfile}

For this example the description file of the region \texttt{myregion} should contain one polygon with the following four coordinates:

\begin{verbatim}
120  20
120  -20
270  -20
270   20
\end{verbatim}
2.6.12. MASKBOX - Mask a box

Synopsis

masklonlatbox,lon1,lon2,lat1,lat2  infile outfile
maskindexbox,IDX1,IDX2,IDX1,IDX2  infile outfile

Description

Masks grid cells inside a lon/lat or index box. The elements inside the box are untouched, the elements outside are set to missing value. All input fields need to have the same horizontal grid. Use sellonlatbox or selindexbox if only the data inside the box are needed.

Operators

masklonlatbox  Mask a longitude/latitude box
Masks grid cells inside a lon/lat box. The user must specify the longitude and latitude of the edges of the box. Only those grid cells are considered whose grid center lies within the lon/lat box. For rotated lon/lat grids the parameters must be specified in rotated coordinates.

maskindexbox  Mask an index box
Masks grid cells within an index box. The user must specify the indices of the edges of the box. The index of the left edge can be greater then the one of the right edge. Use negative indexing to start from the end. The input grid must be a regular lon/lat or a 2D curvilinear grid.

Parameter

lon1  FLOAT  Western longitude
lon2  FLOAT  Eastern longitude
lat1  FLOAT  Southern or northern latitude
lat2  FLOAT  Northern or southern latitude
IDX1  INTEGER  Index of first longitude
IDX2  INTEGER  Index of last longitude
IDX1  INTEGER  Index of first latitude
IDX2  INTEGER  Index of last latitude

Example

To mask the region with the longitudes from 120E to 90W and latitudes from 20N to 20S on all input fields use:

```
cdo masklonlatbox,120,-90,20,-20 infile outfile
```

If the input dataset has fields on a Gaussian N16 grid, the same box can be masked with maskindexbox by:

```
cdo maskindexbox,23,48,13,20 infile outfile
```
2.6.13. SETBOX - Set a box to constant

Synopsis

\begin{verbatim}
setclonlatbox,c,lon1,lon2,lat1,lat2 infile outfile
setcindexbox,c,idx1,idx2,idy1,idy2 infile outfile
\end{verbatim}

Description

Sets a box of the rectangularly understood field to a constant value. The elements outside the box are untouched, the elements inside are set to the given constant. All input fields need to have the same horizontal grid.

Operators

\begin{itemize}
  \item \texttt{setclonlatbox} \hspace{1em} Set a longitude/latitude box to constant
  \hspace{1em} Sets the values of a longitude/latitude box to a constant value. The user has to give the longitudes and latitudes of the edges of the box.
  \item \texttt{setcindexbox} \hspace{1em} Set an index box to constant
  \hspace{1em} Sets the values of an index box to a constant value. The user has to give the indices of the edges of the box. The index of the left edge can be greater than the one of the right edge.
\end{itemize}

Parameter

\begin{verbatim}
c FLOAT Constant
lon1 FLOAT Western longitude
lon2 FLOAT Eastern longitude
lat1 FLOAT Southern or northern latitude
lat2 FLOAT Northern or southern latitude
idx1 INTEGER Index of first longitude
idx2 INTEGER Index of last longitude
idy1 INTEGER Index of first latitude
idy2 INTEGER Index of last latitude
\end{verbatim}

Example

To set all values in the region with the longitudes from 120E to 90W and latitudes from 20N to 20S to the constant value -1.23 use:

\begin{verbatim}
cdo setclonlatbox,-1.23,120,-90,20,-20 infile outfile
\end{verbatim}

If the input dataset has fields on a Gaussian N16 grid, the same box can be set with \texttt{setcindexbox} by:

\begin{verbatim}
cdo setcindexbox,-1.23,23,48,13,20 infile outfile
\end{verbatim}
2.6.14. ENLARGE - Enlarge fields

Synopsis

```
enlarge,grid infile outfile
```

Description

Enlarge all fields of `infile` to a user given horizontal grid. Normally only the last field element is used for the enlargement. If however the input and output grid are regular lon/lat grids, a zonal or meridional enlargement is possible. Zonal enlargement takes place, if the xsize of the input field is 1 and the ysize of both grids are the same. For meridional enlargement the ysize have to be 1 and the xsize of both grids should have the same size.

Parameter

```
grid       STRING       Target grid description file or name
```

Example

Assumed you want to add two datasets. The first dataset is a field on a global grid (n field elements) and the second dataset is a global mean (1 field element). Before you can add these two datasets the second dataset have to be enlarged to the grid size of the first dataset:

```
cdo enlarge,infile1 infile2 tmpfile
cdo add infile1 tmpfile outfile
```

Or shorter using operator piping:

```
cdo add infile1 -enlarge,infile1 infile2 outfile
```
2.6.15. SETMISS - Set missing value

Synopsis

setmissval, newmiss infile outfile
setctomiss, c infile outfile
setmisstoc, c infile outfile
setrtomiss, rmin, rmax infile outfile
setvrange, rmin, rmax infile outfile
setmisstonn infile outfile
setmisstodis[, neighbors] infile outfile

Description

This module sets part of a field to missing value or missing values to a constant value. Which part of the field is set depends on the chosen operator.

Operators

setmissval  Set a new missing value
\[ o(t, x) = \begin{cases} 
\text{newmiss} & \text{if } i(t, x) = \text{miss} \\
 i(t, x) & \text{if } i(t, x) \neq \text{miss} 
\end{cases} \]

setctomiss  Set constant to missing value
\[ o(t, x) = \begin{cases} 
\text{miss} & \text{if } i(t, x) = c \\
 i(t, x) & \text{if } i(t, x) \neq c 
\end{cases} \]

setmisstoc  Set missing value to constant
\[ o(t, x) = \begin{cases} 
 c & \text{if } i(t, x) = \text{miss} \\
 i(t, x) & \text{if } i(t, x) \neq \text{miss} 
\end{cases} \]

setrtomiss  Set range to missing value
\[ o(t, x) = \begin{cases} 
\text{miss} & \text{if } i(t, x) \geq rmin \land i(t, x) \leq rmax \\
i(t, x) & \text{if } i(t, x) < rmin \lor i(t, x) > rmax 
\end{cases} \]

setvrange  Set valid range
\[ o(t, x) = \begin{cases} 
\text{miss} & \text{if } i(t, x) < rmin \lor i(t, x) > rmax \\
i(t, x) & \text{if } i(t, x) \geq rmin \land i(t, x) \leq rmax 
\end{cases} \]

setmisstonn  Set missing value to nearest neighbor
Set all missing values to the nearest non missing value.
\[ o(t, x) = \begin{cases} 
i(t, y) & \text{if } i(t, x) = \text{miss} \land i(t, y) \neq \text{miss} \\
i(t, x) & \text{if } i(t, x) \neq \text{miss} 
\end{cases} \]

setmisstodis  Set missing value to distance-weighted average
Set all missing values to the distance-weighted average of the nearest non missing values. The default number of nearest neighbors is 4.

Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>neighbors</td>
<td>INTEGER</td>
<td>Number of nearest neighbors</td>
</tr>
<tr>
<td>newmiss</td>
<td>FLOAT</td>
<td>New missing value</td>
</tr>
<tr>
<td>c</td>
<td>FLOAT</td>
<td>Constant</td>
</tr>
<tr>
<td>rmin</td>
<td>FLOAT</td>
<td>Lower bound</td>
</tr>
<tr>
<td>rmax</td>
<td>FLOAT</td>
<td>Upper bound</td>
</tr>
</tbody>
</table>
Example

setrtomiss

Assume an input dataset has one field with temperatures in the range from 246 to 304 Kelvin. To set all values below 273.15 Kelvin to missing value use:

```
cdo setrtomiss,0,273.15 infile outfile
```

Result of 'cdo info infile':

<table>
<thead>
<tr>
<th>-1</th>
<th>Date</th>
<th>Time</th>
<th>Code</th>
<th>Level</th>
<th>Size</th>
<th>Miss : Minimum</th>
<th>Mean</th>
<th>Maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1987−12−31</td>
<td>12:00:00</td>
<td>139</td>
<td></td>
<td>2048</td>
<td>0 : 246.27</td>
<td>276.75</td>
<td>303.71</td>
</tr>
</tbody>
</table>

Result of 'cdo info outfile':

<table>
<thead>
<tr>
<th>-1</th>
<th>Date</th>
<th>Time</th>
<th>Code</th>
<th>Level</th>
<th>Size</th>
<th>Miss : Minimum</th>
<th>Mean</th>
<th>Maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1987−12−31</td>
<td>12:00:00</td>
<td>139</td>
<td></td>
<td>2048</td>
<td>871 : 273.16</td>
<td>287.08</td>
<td>303.71</td>
</tr>
</tbody>
</table>

setmisstonn

Set all missing values to the nearest non missing value:

```
cdo setmisstonn infile outfile
```

Below is a schematic illustration of this example:

On the left side is input data with missing values in grey and on the right side the result with the filled missing values.
2.6.16. SETGRIDCELL - Set the value of a grid cell

Synopsis

```
setgridcell, params infile outfile
```

Description

This operator sets the value of the selected grid cells. The grid cells can be selected by a comma-separated list of grid cell indices or a mask. The mask is read from a data file, which may contain only one field. If no grid cells are selected, all values are set.

Parameter

- **value**  
  FLOAT  
  Value of the grid cell

- **cell**  
  INTEGER  
  Comma-separated list of grid cell indices

- **mask**  
  STRING  
  Name of the data file which contains the mask
2.7. Arithmetic

This section contains modules to arithmetically process datasets.

Here is a short overview of all operators in this section:

- **expr**: Evaluate expressions
- **exprf**: Evaluate expressions script
- **aexpr**: Evaluate expressions and append results
- **aexprf**: Evaluate expression script and append results
- **abs**: Absolute value
- **int**: Integer value
- **nint**: Nearest integer value
- **pow**: Power
- **sqr**: Square
- **sqrt**: Square root
- **exp**: Exponential
- **ln**: Natural logarithm
- **log10**: Base 10 logarithm
- **sin**: Sine
- **cos**: Cosine
- **tan**: Tangent
- **asin**: Arc sine
- **acos**: Arc cosine
- **atan**: Arc tangent
- **reci**: Reciprocal value
- **not**: Logical NOT
- **addc**: Add a constant
- **subc**: Subtract a constant
- **mulc**: Multiply with a constant
- **divc**: Divide by a constant
- **minc**: Minimum of a field and a constant
- **maxc**: Maximum of a field and a constant
- **add**: Add two fields
- **sub**: Subtract two fields
- **mul**: Multiply two fields
- **div**: Divide two fields
- **min**: Minimum of two fields
- **max**: Maximum of two fields
- **atan2**: Arc tangent of two fields
- **dayadd**: Add daily time series
- **daysub**: Subtract daily time series
- **daymul**: Multiply daily time series
- **daydiv**: Divide daily time series
- **monadd**: Add monthly time series
- **monsunb**: Subtract monthly time series
- **monmul**: Multiply monthly time series
- **mondiv**: Divide monthly time series

2.7.1. EXPR - Evaluate expressions

Synopsis

expr,instr infile outfile
exprf,filename infile outfile
aexpr,instr infile outfile
aexprf,filename infile outfile

Description

This module arithmetically processes every timestep of the input dataset. Each individual assignment statement have to end with a semi-colon. The special key _ALL_ is used as a template. A statement with a template is replaced for all variable names. Unlike regular variables, temporary variables are never written to the output stream. To define a temporary variable simply prefix the variable name with an underscore (e.g. _varname) when the variable is declared.

The following operators are supported:

<table>
<thead>
<tr>
<th>Operator</th>

</tbody>
</table>

The following functions are supported:

Math intrinsics:

abs(x)  Absolute value of x
floor(x) Round to largest integral value not greater than x
ceil(x)  Round to smallest integral value not less than x
float(x) 32-bit float value of x
int(x)  Integer value of x
nint(x) Nearest integer value of x
sqr(x)  Square of x
sqrt(x)  Square Root of x
exp(x)  Exponential of x

<td>Timestep number (1 to N)</td>
</tr>
<tr>
<td>cdate()</td>
<td>Verification date as YYYYMMDD</td>
</tr>
<tr>
<td>ctime()</td>
<td>Verification time as HHMMSS.millisecond</td>
</tr>
<tr>
<td>cdeltat()</td>
<td>Difference between current and last timestep in seconds</td>
</tr>
<tr>
<td>cday()</td>
<td>Day as DD</td>
</tr>
<tr>
<td>cmonth()</td>
<td>Month as MM</td>
</tr>
<tr>
<td>cyear()</td>
<td>Year as YYYY</td>
</tr>
</tbody>
</table>
csecond() Second as SS.millisecond

cminute() Minute as MM

chour() Hour as HH

Constants:

ngp(x) Number of horizontal grid points

nlev(x) Number of vertical levels

size(x) Total number of elements (ngp(x)*nlev(x))

missval(x) Returns the missing value of variable x

Statistical values over a field:

fldmin(x), fldmax(x), fldrange(x), fldsum(x), fldmean(x), fldavg(x), fldstd(x), fldstd1(x), fldvar(x),
fldvar1(x), fldskew(x), fldkurt(x), fldmedian(x)

Zonal statistical values for regular 2D grids:

zonmin(x), zonmax(x), zonrange(x), zonsum(x), zonmean(x), zonavg(x), zonstd(x), zonstd1(x), zon-
var(x), zonvar1(x), zonskew(x), zonkurt(x), zonmedian(x)

Vertical statistical values:

vertmin(x), vertmax(x), vertrange(x), vertsum(x), vertmean(x), vertavg(x), vertstd(x), vertstd1(x),
vertvar(x), vertvar1(x)

Miscellaneous:

sellevel(x,k) Select level k of variable x

sellevelidx(x,k) Select level index k of variable x

sellevelrange(x,k1,k2) Select all levels of variable x in the range k1 to k2

sellevelidxrange(x,k1,k2) Select all level indices of variable x in the range k1 to k2

remove(x) Remove variable x from output stream

Operators

expr Evaluate expressions
The processing instructions are read from the parameter.

exprf Evaluate expressions script
Contrary to expr the processing instructions are read from a file.

aexpr Evaluate expressions and append results
Same as expr, but keep input variables and append results

aexprf Evaluate expression script and append results
Same as exprf, but keep input variables and append results

Parameter

instr STRING Processing instructions (need to be ‘quoted’ in most cases)

filename STRING File with processing instructions

Note

If the input stream contains duplicate entries of the same variable name then the last one is used.
Example

Assume an input dataset contains at least the variables 'aprl', 'aprc' and 'ts'. To create a new variable 'var1' with the sum of 'aprl' and 'aprc' and a variable 'var2' which convert the temperature 'ts' from Kelvin to Celsius use:

```
cdo expr,'var1=aprl+aprc;var2=ts-273.15;' infile outfile
```

The same example, but the instructions are read from a file:

```
cdo exprf,myexpr infile outfile
```

The file `myexpr` contains:

```
var1 = aprl + aprc;
var2 = ts - 273.15;
```
2.7.2. MATH - Mathematical functions

Synopsis

<operator> infile outfile

Description

This module contains some standard mathematical functions. All trigonometric functions calculate with radians.

Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs</td>
<td>Absolute value</td>
</tr>
<tr>
<td>int</td>
<td>Integer value</td>
</tr>
<tr>

</tr>
<tr>
<td>pow</td>
<td>Power</td>
</tr>
<tr>
<td>sqr</td>
<td>Square</td>
</tr>
<tr>
<td>sqrt</td>
<td>Square root</td>
</tr>
<tr>
<td>exp</td>
<td>Exponential</td>
</tr>
<tr>
<td>ln</td>
<td>Natural logarithm</td>
</tr>
<tr>
<td>log10</td>
<td>Base 10 logarithm</td>
</tr>
<tr>
<td>sin</td>
<td>Sine</td>
</tr>
<tr>
<td>cos</td>
<td>Cosine</td>
</tr>
<tr>
<td>tan</td>
<td>Tangent</td>
</tr>
<tr>
<td>asin</td>
<td>Arc sine</td>
</tr>
<tr>
<td>acos</td>
<td>Arc cosine</td>
</tr>
<tr>
<td>atan</td>
<td>Arc tangent</td>
</tr>
<tr>
<td>reci</td>
<td>Reciprocal value</td>
</tr>
<tr>
<td>not</td>
<td>Logical NOT</td>
</tr>
</tbody>
</table>

Example:

\[
o(t, x) = \begin{cases} 1, & \text{if } x = 0; \\ 0, & \text{else} \end{cases}
\]
Example

To calculate the square root for all field elements use:

```plaintext
cdo sqrt infile outfile
```
2.7.3. ARITHC - Arithmetic with a constant

Synopsis

<operator>,c infile outfile

Description

This module performs simple arithmetic with all field elements of a dataset and a constant. The fields in outfile inherit the meta data from infile.

Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>addc</td>
<td>Add a constant</td>
<td><code>cdo addc,-273.15 infile outfile</code></td>
</tr>
<tr>
<td>subc</td>
<td>Subtract a constant</td>
<td></td>
</tr>
<tr>
<td>mulc</td>
<td>Multiply with a constant</td>
<td></td>
</tr>
<tr>
<td>divc</td>
<td>Divide by a constant</td>
<td></td>
</tr>
<tr>
<td>minc</td>
<td>Minimum of a field and a constant</td>
<td></td>
</tr>
<tr>
<td>maxc</td>
<td>Maximum of a field and a constant</td>
<td></td>
</tr>
</tbody>
</table>

Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>FLOAT</td>
<td>Constant</td>
</tr>
</tbody>
</table>

Example

To sum all input fields with the constant -273.15 use:

```
cdo addc,-273.15 infile outfile
```
2.7.4. ARITH - Arithmetic on two datasets

Synopsis

<operator> infile1 infile2 outfile

Description

This module performs simple arithmetic of two datasets. The number of fields in infile1 should be the same as in infile2. The fields in outfile inherit the meta data from infile1. All operators in this module simply process one field after the other from the two input files. Neither the order of the variables nor the date is checked. One of the input files can contain only one timestep or one variable.

Operators

add  Add two fields
\[ o(t,x) = i_1(t,x) + i_2(t,x) \]
sub  Subtract two fields
\[ o(t,x) = i_1(t,x) - i_2(t,x) \]
mul  Multiply two fields
\[ o(t,x) = i_1(t,x) \times i_2(t,x) \]
div  Divide two fields
\[ o(t,x) = \frac{i_1(t,x)}{i_2(t,x)} \]
min  Minimum of two fields
\[ o(t,x) = \min(i_1(t,x), i_2(t,x)) \]
max  Maximum of two fields
\[ o(t,x) = \max(i_1(t,x), i_2(t,x)) \]
atan2  Arc tangent of two fields
The atan2 operator calculates the arc tangent of two fields. The result is in radians, which is between -PI and PI (inclusive).
\[ o(t,x) = \text{atan2}(i_1(t,x), i_2(t,x)) \]

Example

To sum all fields of the first input file with the corresponding fields of the second input file use:

\begin{verbatim}
cdo add infile1 infile2 outfile
\end{verbatim}
2.7.5. DAYARITH - Daily arithmetic

Synopsis

\(<\text{operator}>\) \text{infile1 infile2 outfile}

Description

This module performs simple arithmetic of a time series and one timestep with the same day, month and year. For each field in \text{infile1} the corresponding field of the timestep in \text{infile2} with the same day, month and year is used. The header information in \text{infile1} have to be the same as in \text{infile2}. Usually \text{infile2} is generated by an operator of the module \text{DAYSTAT}.

Operators

- **dayadd**: Add daily time series
  Adds a time series and a daily time series.
- **daysub**: Subtract daily time series
  Subtracts a time series and a daily time series.
- **daymul**: Multiply daily time series
  Multiplies a time series and a daily time series.
- **daydiv**: Divide daily time series
  Divides a time series and a daily time series.

Example

To subtract a daily time average from a time series use:

```
  cdo daysub infile -dayavg infile outfile
```
**2.7.6. MONARITH - Monthly arithmetic**

**Synopsis**

\[ <\text{operator}> \text{infile1} \text{infile2} \text{outfile} \]

**Description**

This module performs simple arithmetic of a time series and one timestep with the same month and year. For each field in `infile1` the corresponding field of the timestep in `infile2` with the same month and year is used. The header information in `infile1` have to be the same as in `infile2`. Usually ` infile2` is generated by an operator of the module MONSTAT.

**Operators**

- **monadd**: Add monthly time series
  
  Adds a time series and a monthly time series.

- **monsunb**: Subtract monthly time series
  
  Subtracts a time series and a monthly time series.

- **monmul**: Multiply monthly time series
  
  Multiplies a time series and a monthly time series.

- **mondiv**: Divide monthly time series
  
  Divides a time series and a monthly time series.

**Example**

To subtract a monthly time average from a time series use:

```
cdo monsub infile -monavg infile outfile
```
2.7.7. YEARARITH - Yearly arithmetic

Synopsis

<operator> infile1 infile2 outfile

Description

This module performs simple arithmetic of a time series and one timestep with the same year. For each field in infile1 the corresponding field of the timestep in infile2 with the same year is used. The header information in infile1 have to be the same as in infile2. Usually infile2 is generated by an operator of the module YEARSTAT.

Operators

- yearadd: Add yearly time series
- yearsub: Subtract yearly time series
- yearmul: Multiply yearly time series
- yeardiv: Divide yearly time series

Example

To subtract a yearly time average from a time series use:

```cdo yearsub infile -yearavg infile outfile```
2.7.8. YHOURARITH - Multi-year hourly arithmetic

Synopsis

\[ <\text{operator}> \text{ infile1 infile2 outfile} \]

Description

This module performs simple arithmetic of a time series and one timestep with the same hour and day of year. For each field in \text{infile1} the corresponding field of the timestep in \text{infile2} with the same hour and day of year is used. The header information in \text{infile1} have to be the same as in \text{infile2}. Usually \text{infile2} is generated by an operator of the module \text{Y HOURSTAT}.

Operators

\begin{itemize}
  \item \textit{yhouradd} \hspace{1em} Add multi-year hourly time series
  \hspace{1em} Adds a time series and a multi-year hourly time series.
  \item \textit{yhoursub} \hspace{1em} Subtract multi-year hourly time series
  \hspace{1em} Subtracts a time series and a multi-year hourly time series.
  \item \textit{yhournul} \hspace{1em} Multiply multi-year hourly time series
  \hspace{1em} Multiplies a time series and a multi-year hourly time series.
  \item \textit{yhourdiv} \hspace{1em} Divide multi-year hourly time series
  \hspace{1em} Divides a time series and a multi-year hourly time series.
\end{itemize}

Example

To subtract a multi-year hourly time average from a time series use:

\begin{verbatim}
  cdo yhoursub infile -yhouravg infile outfile
\end{verbatim}
2.7.9. YDAYARITH - Multi-year daily arithmetic

Synopsis

<operator> infile1 infile2 outfile

Description

This module performs simple arithmetic of a time series and one timestep with the same day of year. For each field in infile1 the corresponding field of the timestep in infile2 with the same day of year is used. The header information in infile1 have to be the same as in infile2. Usually infile2 is generated by an operator of the module YDAYSTAT.

Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ydayadd</td>
<td>Add multi-year daily time series</td>
</tr>
<tr>
<td></td>
<td>Adds a time series and a multi-year daily time series.</td>
</tr>
<tr>
<td>ydaysub</td>
<td>Subtract multi-year daily time series</td>
</tr>
<tr>
<td></td>
<td>Subtracts a time series and a multi-year daily time series.</td>
</tr>
<tr>
<td>ydaymul</td>
<td>Multiply multi-year daily time series</td>
</tr>
<tr>
<td></td>
<td>Multiplies a time series and a multi-year daily time series.</td>
</tr>
<tr>
<td>ydaydiv</td>
<td>Divide multi-year daily time series</td>
</tr>
<tr>
<td></td>
<td>Divides a time series and a multi-year daily time series.</td>
</tr>
</tbody>
</table>

Example

To subtract a multi-year daily time average from a time series use:

```
cdo ydaysub infile -ydayavg infile outfile
```
2.7.10. YMONARITH - Multi-year monthly arithmetic

Synopsis

<operator> infile1 infile2 outfile

Description

This module performs simple arithmetic of a time series and one timestep with the same month of year. For each field in infile1 the corresponding field of the timestep in infile2 with the same month of year is used. The header information in infile1 have to be the same as in infile2. Usually infile2 is generated by an operator of the module YMONSTAT.

Operators

ymonadd  Add multi-year monthly time series
          Adds a time series and a multi-year monthly time series.
ymonsub  Subtract multi-year monthly time series
          Subtracts a time series and a multi-year monthly time series.
ymonmul  Multiply multi-year monthly time series
          Multiplies a time series and a multi-year monthly time series.
ymondiv  Divide multi-year monthly time series
          Divides a time series and a multi-year monthly time series.

Example

To subtract a multi-year monthly time average from a time series use:

     cdo ymonsub infile -ymonavg infile outfile
2.7.11. **YSEASARITH - Multi-year seasonal arithmetic**

**Synopsis**

```latex
<operator> infile1 infile2 outfile
```

**Description**

This module performs simple arithmetic of a time series and one timestep with the same season. For each field in `infile1` the corresponding field of the timestep in `infile2` with the same season is used. The header information in `infile1` have to be the same as in `infile2`. Usually `infile2` is generated by an operator of the module **YSEASSTAT**.

**Operators**

- **yseasadd**: Add multi-year seasonal time series
  Adds a time series and a multi-year seasonal time series.
- **yseassub**: Subtract multi-year seasonal time series
  Subtracts a time series and a multi-year seasonal time series.
- **yseasmul**: Multiply multi-year seasonal time series
  Multiplies a time series and a multi-year seasonal time series.
- **yseasdiv**: Divide multi-year seasonal time series
  Divides a time series and a multi-year seasonal time series.

**Example**

To subtract a multi-year seasonal time average from a time series use:

```
cdo yseassub infile -yseasavg infile outfile
```
2.7.12. ARITHDAYS - Arithmetic with days

Synopsis

<operator> infile outfile

Description

This module multiplies or divides each timestep of a dataset with the corresponding days per month or days per year. The result of these functions depends on the used calendar of the input data.

Operators

- **muldpm** Multiply with days per month
  \[ o(t, x) = i(t, x) \times \text{days\_per\_month} \]
- **divdpm** Divide by days per month
  \[ o(t, x) = i(t, x) / \text{days\_per\_month} \]
- **muldpy** Multiply with days per year
  \[ o(t, x) = i(t, x) \times \text{days\_per\_year} \]
- **divdpy** Divide by days per year
  \[ o(t, x) = i(t, x) / \text{days\_per\_year} \]

2.7.13. ARITHLAT - Arithmetic with latitude

Synopsis

<operator> infile outfile

Description

This module multiplies or divides each field element with the cosine of the latitude.

Operators

- **mulcoslat** Multiply with the cosine of the latitude
  \[ o(t, x) = i(t, x) \times \cos(\text{latitude}(x)) \]
- **divcoslat** Divide by cosine of the latitude
  \[ o(t, x) = i(t, x) / \cos(\text{latitude}(x)) \]
2.8. Statistical values

This section contains modules to compute statistical values of datasets. In this program there is the different notion of "mean" and "average" to distinguish two different kinds of treatment of missing values. While computing the mean, only the not missing values are considered to belong to the sample with the side effect of a probably reduced sample size. Computing the average is just adding the sample members and divide the result by the sample size. For example, the mean of 1, 2, miss and 3 is $(1+2+3)/3 = 2$, whereas the average is $(1+2+miss+3)/4 = miss/4 = miss$. If there are no missing values in the sample, the average and the mean are identical.

**CDO** is using the verification time to identify the time range for temporal statistics. The time bounds are never used!

In this section the abbreviations as in the following table are used:

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>$\sum_{i=1}^{n} x_i$</td>
</tr>
<tr>
<td>mean resp. avg</td>
<td>$n^{-1} \sum_{i=1}^{n} x_i$</td>
</tr>
<tr>
<td>mean resp. avg weighted by</td>
<td>$\left( \sum_{j=1}^{n} w_j \right)^{-1} \sum_{i=1}^{n} w_i x_i$</td>
</tr>
<tr>
<td>Variance</td>
<td>$n^{-1} \sum_{i=1}^{n} (x_i - \bar{x})^2$</td>
</tr>
<tr>
<td>var weighted by</td>
<td>$\left( \sum_{j=1}^{n} w_j \right)^{-1} \sum_{i=1}^{n} w_i \left( x_i - \left( \sum_{j=1}^{n} w_j \right)^{-1} \sum_{j=1}^{n} w_j x_j \right)^2$</td>
</tr>
<tr>
<td>Standard deviation</td>
<td>$\sqrt{\frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^2}$</td>
</tr>
<tr>
<td>std weighted by</td>
<td>$\sqrt{\frac{1}{(n-1)^{-1} \sum_{i=1}^{n} (x_i - \bar{x})^2}}$</td>
</tr>
<tr>
<td>median</td>
<td>$\begin{cases} x_{\frac{n+1}{2}} &amp; \text{if } n \text{ is odd} \ \frac{1}{2} \left( x_{\frac{n}{2}} + x_{\frac{n}{2}+1} \right) &amp; \text{if } n \text{ is even} \end{cases}$</td>
</tr>
</tbody>
</table>
**Skewness**

-skew-

\[ \overline{skew} = \frac{\sum_{i=1}^{n} (x_i - \overline{x})}{s^3} \]

**Kurtosis**

-kurt-

\[ \overline{kurt} = \frac{\sum_{i=1}^{n} (x_i - \overline{x})^4}{s^4} \]

**Cumulative Ranked Probability Score**

-crps-

\[ \text{crps} = \int_{-\infty}^{\infty} [H(x_1) - \text{cdf}([x_2 \ldots x_n])|_r]^2 \text{d}r \]

with \( \text{cdf}(X)|_r \) being the cumulative distribution function of \( \{x_i, i = 2 \ldots n\} \) at \( r \)

and \( H(x) \) the Heaviside function jumping at \( x \).

Here is a short overview of all operators in this section:

- **timcumsum**: Cumulative sum over all timesteps
- **consecsum**: Consecutive Sum
- **consects**: Consecutive Timesteps
- **varsmin**: Variables minimum
- **varsmax**: Variables maximum
- **varssrange**: Variables range
- **varssum**: Variables sum
- **varsmean**: Variables mean
- **varsavg**: Variables average
- **varsstd**: Variables standard deviation
- **varsstd1**: Variables standard deviation (n-1)
- **varsvvar**: Variables variance
- **varsvar1**: Variables variance (n-1)
- **ensmin**: Ensemble minimum
- **ensmax**: Ensemble maximum
- **ensrange**: Ensemble range
- **enssum**: Ensemble sum
- **ensmean**: Ensemble mean
- **ensavg**: Ensemble average
- **ensstd**: Ensemble standard deviation
- **ensstd1**: Ensemble standard deviation (n-1)
- **ensvar**: Ensemble variance
- **ensvar1**: Ensemble variance (n-1)
- **ensskew**: Ensemble skewness
- **enskurt**: Ensemble kurtosis
- **ensmedian**: Ensemble median
- **enspctl**: Ensemble percentiles
- **ensrkhistspace**: Ranked Histogram averaged over space
- **ensrkhisttime**: Ranked Histogram averaged over time
- **ensroc**: Ensemble Receiver Operating characteristics
- **enscrps**: Ensemble CRPS and decomposition
- **ensbrs**: Ensemble Brier score

2.8.1. TIMCUMSUM - Cumulative sum over all timesteps

Synopsis

\texttt{timcumsum infile outfile}

Description

The timcumsum operator calculates the cumulative sum over all timesteps. Missing values are treated as numeric zero when summing.

\[ o(t, x) = \sum \{ i(t', x), 0 < t' \leq t \} \]

2.8.2. CONSECSTAT - Consecutive timestep periods

Synopsis

\texttt{<operator> infile outfile}

Description

This module computes periods over all timesteps in \texttt{infile} where a certain property is valid. The property can be chosen by creating a mask from the original data, which is the expected input format for operators of this module. Depending on the operator full information about each period or just its length and ending date are computed.

Operators

- \texttt{consecsum} Consecutive Sum
  This operator computes periods of consecutive timesteps similar to a \texttt{runsum}, but periods are finished, when the mask value is 0. That way multiple periods can be found. Timesteps from the input are preserved. Missing values are handled like 0, i.e. finish periods of consecutive timesteps.

- \texttt{consects} Consecutive Timesteps
  In contrast to the operator above consects only computes the length of each period together with its last timestep. To be able to perform statistical analysis like min, max or mean, everything else is set to missing value.

Example

For a given time series of daily temperatures, the periods of summer days can be calculated with inplace masking the input field:

\begin{verbatim}
cdo consects -gtc,20.0 infile1 outfile
\end{verbatim}
2.8.3. **VARSSTAT - Statistical values over all variables**

**Synopsis**

```plaintext
<operator> infile outfile
```

**Description**

This module computes statistical values over all variables for each timestep. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation is written to `outfile`. All input variables need to have the same gridsize and the same number of levels.

**Operators**

- **varsmin** Variables minimum
  For every timestep the minimum over all variables is computed.
- **varsmax** Variables maximum
  For every timestep the maximum over all variables is computed.
- **varsrange** Variables range
  For every timestep the range over all variables is computed.
- **varssum** Variables sum
  For every timestep the sum over all variables is computed.
- **varsmean** Variables mean
  For every timestep the mean over all variables is computed.
- **varsavg** Variables average
  For every timestep the average over all variables is computed.
- **varsstd** Variables standard deviation
  For every timestep the standard deviation over all variables is computed. Normalize by n.
- **varsstd1** Variables standard deviation (n-1)
  For every timestep the standard deviation over all variables is computed. Normalize by (n-1).
- **varsvar** Variables variance
  For every timestep the variance over all variables is computed. Normalize by n.
- **varsvar1** Variables variance (n-1)
  For every timestep the variance over all variables is computed. Normalize by (n-1).
2.8.4. ENSSTAT - Statistical values over an ensemble

Synopsis

<operator> infiles outfile
enspclt,p infiles outfile

Description

This module computes statistical values over an ensemble of input files. Depending on the chosen operator, the minimum, maximum, range, sum, average, standard deviation, variance, skewness, kurtosis, median or a certain percentile over all input files is written to outfile. All input files need to have the same structure with the same variables. The date information of a timestep in outfile is the date of the first input file.

Operators

ensmin  Ensemble minimum
\[ o(t, x) = \min\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensmax  Ensemble maximum
\[ o(t, x) = \max\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensrange  Ensemble range
\[ o(t, x) = \text{range}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

enssum  Ensemble sum
\[ o(t, x) = \sum\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensmean  Ensemble mean
\[ o(t, x) = \text{mean}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensavg  Ensemble average
\[ o(t, x) = \text{avg}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensstd  Ensemble standard deviation
Normalize by n.
\[ o(t, x) = \text{std}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensstd1  Ensemble standard deviation (n-1)
Normalize by (n-1).
\[ o(t, x) = \text{std1}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensvar  Ensemble variance
Normalize by n.
\[ o(t, x) = \text{var}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensvar1  Ensemble variance (n-1)
Normalize by (n-1).
\[ o(t, x) = \text{var1}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensskew  Ensemble skewness
\[ o(t, x) = \text{skew}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

enskurt  Ensemble kurtosis
\[ o(t, x) = \text{kurt}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

ensmedian  Ensemble median
\[ o(t, x) = \text{median}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]

enspclt  Ensemble percentiles
\[ o(t, x) = \text{pth percentile}\{i_1(t, x), i_2(t, x), \ldots, i_n(t, x)\} \]
**Parameter**

\[ p \] **FLOAT** Percentile number in 0, ..., 100

**Note**

Operators of this module need to open all input files simultaneously. The maximum number of open files depends on the operating system!

**Example**

To compute the ensemble mean over 6 input files use:

```
cdo ensmean infile1 infile2 infile3 infile4 infile5 infile6 outfile
```

Or shorter with filename substitution:

```
cdo ensmean infile[1-6] outfile
```

To compute the 50th percentile (median) over 6 input files use:

```
cdo enspctl,50 infile1 infile2 infile3 infile4 infile5 infile6 outfile
```
2.8.5. ENSSTAT2 - Statistical values over an ensemble

Synopsis

\(<operator>\) obsfile ensfiles outfile

Description

This module computes statistical values over the ensemble of ensfiles using obsfile as a reference. Depending on the operator a ranked Histogram or a roc-curve over all Ensembles ensfiles with reference to obsfile is written to outfile. The date and grid information of a timestep in outfile is the date of the first input file. Thus all input files are required to have the same structure in terms of the gridsize, variable definitions and number of timesteps.

All Operators in this module use obsfile as the reference (for instance an observation) whereas ensfiles are understood as an ensemble consisting of n (where n is the number of ensfiles) members.

The operators ensrkhistspace and ensrkhisttime compute Ranked Histograms. Therefor the vertical axis is utilized as the Histogram axis, which prohibits the use of files containing more than one level. The histogram axis has nensfiles+1 bins with level 0 containing for each grid point the number of observations being smaller as all ensembles and level nensfiles+1 indicating the number of observations being larger than all ensembles.

ensrkhistspace computes a ranked histogram at each timestep reducing each horizontal grid to a 1x1 grid and keeping the time axis as in obsfile. Contrary ensrkhistspace computes a histogram at each grid point keeping the horizontal grid for each variable and reducing the time-axis. The time information is that from the last timestep in obsfile.

Operators

- ensrkhistspace: Ranked Histogram averaged over time
- ensrkhisttime: Ranked Histogram averaged over space
- ensroc: Ensemble Receiver Operating characteristics

Example

To compute a rank histogram over 5 input files ensfile1-ensfile5 given an observation in obsfile use:

```
cdo ensrkhisttime obsfile ensfile1 ensfile2 ensfile3 ensfile4 ensfile5 outfile
```

Or shorter with filename substitution:

```
cdo ensrkhisttime obsfile ensfile[1-5] outfile
```
2.8.6. ENSVAL - Ensemble validation tools

Synopsis

\begin{verbatim}
enscrps rfile infiles outfilebase
ensbrs,x rfile infiles outfilebase
\end{verbatim}

Description

This module computes ensemble validation scores and their decomposition such as the Brier and cumulative ranked probability score (CRPS). The first file is used as a reference it can be a climate, observation or reanalysis against which the skill of the ensembles given in infiles is measured. Depending on the operator a number of output files is generated each containing the skill score and its decomposition corresponding to the operator. The output is averaged over horizontal fields using appropriate weights for each level and timestep in rfile.

All input files need to have the same structure with the same variables. The date information of a timestep in outfile is the date of the first input file. The output files are named as <outfilebase>.<type>.<filesuffix>, where <type> depends on the operator and <filesuffix> is determined from the output file type. There are three output files for operator enscrps and four output files for operator ensbrs.

The CRPS and its decomposition into Reliability and the potential CRPS are calculated by an appropriate averaging over the field members (note, that the CRPS does *not* average linearly). In the three output files <type> has the following meaning: crps for the CRPS, reli for the reliability and crpspot for the potential crps. The relation \( CRPS = CRPS_{pot} + RELI \) holds.

The Brier score of the Ensemble given by infiles with respect to the reference given in rfile and the threshold x is calculated. In the four output files <type> has the following meaning: brs for the Brier score w.r.t. threshold x; brsreli for the Brier score reliability w.r.t. threshold x; brsreso for the Brier score resolution w.r.t. threshold x; brsunct for the Brier score uncertainty w.r.t. threshold x. In analogy to the CRPS the following relation holds: \( BRS(x) = RELI(x) - RESO(x) + UNCT(x) \).

The CRPS code decomposition has been verified against the CRAN - ensemble validation package from R. Differences occur when grid-cell area is not uniform as the implementation in R does not account for that.

Operators

\begin{verbatim}
enscrps Ensemble CRPS and decomposition
ensbrs Ensemble Brier score
\end{verbatim}

Example

To compute the field averaged Brier score at x=5 over an ensemble with 5 members ensfile1-5 w.r.t. the reference rfile and write the results to files obase.brs<suff>, obase.brsreli<suff>, obase.brsreso<suff>, obase.brsunct<suff> where <suff> is determined from the output file type, use

\begin{verbatim}
cdo ensbrs,5 rfile ensfile1 ensfile2 ensfile3 ensfile4 ensfile5 obase
\end{verbatim}
or shorter using file name substitution:

\begin{verbatim}
cdo ensbrs,5 rfile ensfile[1-5] obase
\end{verbatim}
2.8.7. FLDSTAT - Statistical values over a field

Synopsis

<operator>,weights infile outfile
fldpctl,p infile outfile

Description

This module computes statistical values of all input fields. A field is a horizontal layer of a data variable. Depending on the chosen operator, the minimum, maximum, range, sum, integral, average, standard deviation, variance, skewness, kurtosis, median or a certain percentile of the field is written to outfile.

Operators

fldmin  Field minimum
For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \min \{ i(t, x'), x_1 < x' \leq x_n \} \]

fldmax  Field maximum
For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \max \{ i(t, x'), x_1 < x' \leq x_n \} \]

fldrange Field range
For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \text{range} \{ i(t, x'), x_1 < x' \leq x_n \} \]

fldsum  Field sum
For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \text{sum} \{ i(t, x'), x_1 < x' \leq x_n \} \]

fldint  Field integral
For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \text{sum} \{ i(t, x') \times \text{cellarea}(x'), x_1 < x' \leq x_n \} \]

fldmean Field mean
For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \text{mean} \{ i(t, x'), x_1 < x' \leq x_n \} \]
weighted by area weights obtained by the input field.

fldavg  Field average
For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \text{avg} \{ i(t, x'), x_1 < x' \leq x_n \} \]
weighted by area weights obtained by the input field.

fldstd  Field standard deviation
Normalize by \( n \). For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \text{std} \{ i(t, x'), x_1 < x' \leq x_n \} \]
weighted by area weights obtained by the input field.

fldstd1 Field standard deviation (n-1)
Normalize by \( n-1 \). For every gridpoint \( x_1, ..., x_n \) of the same field it is:
\[ o(t, 1) = \text{std}1 \{ i(t, x'), x_1 < x' \leq x_n \} \]
weighted by area weights obtained by the input field.
**fldvar**  
Field variance  
Normalize by n. For every gridpoint $x_1, ..., x_n$ of the same field it is:  
$$o(t, 1) = \frac{1}{n-1} \sum_{x_1 < x' \leq x_n} \text{var}\{i(t, x'), x_1 < x' \leq x_n\}$$  
weighted by area weights obtained by the input field.

**fldvar1**  
Field variance (n-1)  
Normalize by (n-1). For every gridpoint $x_1, ..., x_n$ of the same field it is:  
$$o(t, 1) = \frac{1}{n-1} \sum_{x_1 < x' \leq x_n} \text{var}_1\{i(t, x'), x_1 < x' \leq x_n\}$$  
weighted by area weights obtained by the input field.

**fldskew**  
Field skewness  
For every gridpoint $x_1, ..., x_n$ of the same field it is:  
$$o(t, 1) = \text{skew}\{i(t, x'), x_1 < x' \leq x_n\}$$

**fldkurt**  
Field kurtosis  
For every gridpoint $x_1, ..., x_n$ of the same field it is:  
$$o(t, 1) = \text{kurt}\{i(t, x'), x_1 < x' \leq x_n\}$$

**fldmedian**  
Field median  
For every gridpoint $x_1, ..., x_n$ of the same field it is:  
$$o(t, 1) = \text{median}\{i(t, x'), x_1 < x' \leq x_n\}$$

**fldpctl**  
Field percentiles  
For every gridpoint $x_1, ..., x_n$ of the same field it is:  
$$o(t, 1) = p\text{th percentile}\{i(t, x'), x_1 < x' \leq x_n\}$$

**Parameter**

- **weights**  
  **BOOL**  
  weights=FALSE disables weighting by grid cell area [default: weights=TRUE]

- **p**  
  **FLOAT**  
  Percentile number in 0, ..., 100

**Example**

To compute the field mean of all input fields use:

```
cdo fldmean infile outfile
```

To compute the 90th percentile of all input fields use:

```
cdo fldpctl,90 infile outfile
```
2.8.8. ZONSTAT - Zonal statistical values

Synopsis

<operator> infile outfile
zonmean[,zonaldes] infile outfile
zonpctl,p infile outfile

Description

This module computes zonal statistical values of the input fields. Depending on the chosen operator, the zonal minimum, maximum, range, sum, average, standard deviation, variance, skewness, kurtosis, median or a certain percentile of the field is written to outfile. Operators of this module require all variables on the same regular lon/lat grid. Only the zonal mean (zonmean) can be calculated for data on an unstructured grid if the latitude bins are defined with the optional parameter zonaldes.

Operators

zonmin Zonal minimum
For every latitude the minimum over all longitudes is computed.

zonmax Zonal maximum
For every latitude the maximum over all longitudes is computed.

zonrange Zonal range
For every latitude the range over all longitudes is computed.

zonsum Zonal sum
For every latitude the sum over all longitudes is computed.

zonmean Zonal mean
For every latitude the mean over all longitudes is computed. Use the optional parameter zonaldes for data on an unstructured grid.

zonavg Zonal average
For every latitude the average over all longitudes is computed.

zonstd Zonal standard deviation
For every latitude the standard deviation over all longitudes is computed. Normalize by n.

zonstd1 Zonal standard deviation (n-1)
For every latitude the standard deviation over all longitudes is computed. Normalize by (n-1).

zonvar Zonal variance
For every latitude the variance over all longitudes is computed. Normalize by n.

zonvar1 Zonal variance (n-1)
For every latitude the variance over all longitudes is computed. Normalize by (n-1).

zonskew Zonal skewness
For every latitude the skewness over all longitudes is computed.

zonkurt Zonal kurtosis
For every latitude the kurtosis over all longitudes is computed.

zonmedian Zonal median
For every latitude the median over all longitudes is computed.

zonpctl Zonal percentiles
For every latitude the pth percentile over all longitudes is computed.
Parameter

- **p**  FLOAT  Percentile number in 0, ..., 100
- **zonakdes**  STRING  Description of the zonal latitude bins needed for data on an unstructured grid. A predefined zonal description is zonal_<DY>. DY is the increment of the latitudes in degrees.

Example

To compute the zonal mean of all input fields use:

```
cdo zonmean infile outfile
```

To compute the 50th meridional percentile (median) of all input fields use:

```
cdo zonpctl,50 infile outfile
```
2.8.9. MERSTAT - Meridional statistical values

Synopsis

<operator> infile outfile
merpctl,p infile outfile

Description

This module computes meridional statistical values of the input fields. Depending on the chosen operator, the meridional minimum, maximum, range, sum, average, standard deviation, variance, skewness, kurtosis, median or a certain percentile of the field is written to outfile. Operators of this module require all variables on the same regular lon/lat grid.

Operators

mermin  Meridional minimum
For every longitude the minimum over all latitudes is computed.

mermax  Meridional maximum
For every longitude the maximum over all latitudes is computed.

merrange Meridional range
For every longitude the range over all latitudes is computed.

mersum  Meridional sum
For every longitude the sum over all latitudes is computed.

mermean Meridional mean
For every longitude the area weighted mean over all latitudes is computed.

meravg  Meridional average
For every longitude the area weighted average over all latitudes is computed.

merstd  Meridional standard deviation
For every longitude the standard deviation over all latitudes is computed. Normalize by n.

merstd1 Meridional standard deviation (n-1)
For every longitude the standard deviation over all latitudes is computed. Normalize by (n-1).

mervar  Meridional variance
For every longitude the variance over all latitudes is computed. Normalize by n.

mervar1 Meridional variance (n-1)
For every longitude the variance over all latitudes is computed. Normalize by (n-1).

merskew Meridional skewness
For every longitude the skewness over all latitudes is computed.

merkurt Meridional kurtosis
For every longitude the kurtosis over all latitudes is computed.

mermedian Meridional median
For every longitude the median over all latitudes is computed.

merpctl Meridional percentiles
For every longitude the pth percentile over all latitudes is computed.

Parameter

p  FLOAT  Percentile number in 0, ..., 100
Example

To compute the meridional mean of all input fields use:

```
cdo mermean infile outfile
```

To compute the 50th meridional percentile (median) of all input fields use:

```
cdo merpctl,50 infile outfile
```
2.8.10. GRIDBOXSTAT - Statistical values over grid boxes

Synopsis

<operator>,nx,ny infile outfile

Description

This module computes statistical values over surrounding grid boxes. Depending on the chosen operator, the minimum, maximum, range, sum, average, standard deviation, variance, skewness, kurtosis or median of the neighboring grid boxes is written to outfile. All gridbox operators only work on quadrilateral curvilinear grids.

Operators

Example

To compute the mean over 10x10 grid boxes of the input field use:

cdo gridboxmean,10,10 infile outfile
2.8.11. REMAPSTAT - Remaps source points to target cells

Synopsis

```
<operator>,grid infile outfile
```

Description

This module maps source points to target cells by calculating a statistical value from the source points. Each target cell contains the statistical value from all source points within that target cell. If there are no source points within a target cell, it gets a missing value. The target grid must be regular lon/lat or Gaussian. Depending on the chosen operator the minimum, maximum, range, sum, average, variance, standard deviation, skewness, kurtosis or median of source points is computed.

Operators

- `remapmin` Remap minimum
  Minimum value of the source points.
- `remapmax` Remap maximum
  Maximum value of the source points.
- `remaprange` Remap range
  Range (max-min value) of the source points.
- `remapsum` Remap sum
  Sum of the source points.
- `remapmean` Remap mean
  Mean of the source points.
- `remapavg` Remap average
  Average of the source points.
- `remapstd` Remap standard deviation
  Standard deviation of the source points. Normalize by n.
- `remapstd1` Remap standard deviation (n-1)
  Standard deviation of the source points. Normalize by (n-1).
- `remapvar` Remap variance
  Variance of the source points. Normalize by n.
- `remapvar1` Remap variance (n-1)
  Variance of the source points. Normalize by (n-1).
- `remapskew` Remap skewness
  Skewness of the source points.
- `remapkurt` Remap kurtosis
  Kurtosis of the source points.
- `remapmedian` Remap median
  Median of the source points.

Parameter

- `grid` STRING Target grid description file or name
Example

To compute the mean over source points within the target cells, use:

```
cdo remapmean,<targetgrid> infile outfile
```

If some of the target cells contain missing values, use the Operator `setmisstonn` to fill these missing values with the nearest neighbor cell:

```
cdo setmisstonn -remapmean,<targetgrid> infile outfile
```
2.8.12. VERTSTAT - Vertical statistical values

Synopsis

<operator>,weights infile outfile

Description

This module computes statistical values over all levels of the input variables. According to chosen operator the vertical minimum, maximum, range, sum, average, variance or standard deviation is written to outfile.

Operators

- **vertmin**  
  Vertical minimum  
  For every gridpoint the minimum over all levels is computed.

- **vertmax**  
  Vertical maximum  
  For every gridpoint the maximum over all levels is computed.

- **vertrange**  
  Vertical range  
  For every gridpoint the range over all levels is computed.

- **vertsum**  
  Vertical sum  
  For every gridpoint the sum over all levels is computed.

- **vertmean**  
  Vertical mean  
  For every gridpoint the layer weighted mean over all levels is computed.

- **vertavg**  
  Vertical average  
  For every gridpoint the layer weighted average over all levels is computed.

- **vertstd**  
  Vertical standard deviation  
  For every gridpoint the standard deviation over all levels is computed. Normalize by n.

- **vertstd1**  
  Vertical standard deviation (n-1)  
  For every gridpoint the standard deviation over all levels is computed. Normalize by (n-1).

- **vertvar**  
  Vertical variance  
  For every gridpoint the variance over all levels is computed. Normalize by n.

- **vertvar1**  
  Vertical variance (n-1)  
  For every gridpoint the variance over all levels is computed. Normalize by (n-1).

Parameter

- **weights**  
  **BOOL**  
  weights=FALSE disables weighting by layer thickness [default: weights=TRUE]

Example

To compute the vertical sum of all input variables use:

```
  cdo vertsum infile outfile
```
2.8.13. TIMSELSTAT - Time range statistical values

Synopsis

\(<\text{operator}>,\text{nsets},\text{noffset},\text{nskip}\) infile outfile

Description

This module computes statistical values for a selected number of timesteps. According to the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of the selected timesteps is written to outfile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>.

Operators

- **timselmin** Time selection minimum
  
  For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \min\{i(t', x), t_1 < t' \leq t_n\} \]

- **timselmax** Time selection maximum
  
  For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \max\{i(t', x), t_1 < t' \leq t_n\} \]

- **timselrange** Time selection range
  
  For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \text{range}\{i(t', x), t_1 < t' \leq t_n\} \]

- **timselsum** Time selection sum
  
  For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \sum\{i(t', x), t_1 < t' \leq t_n\} \]

- **timselmean** Time selection mean
  
  For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \text{mean}\{i(t', x), t_1 < t' \leq t_n\} \]

- **timselavg** Time selection average
  
  For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \text{avg}\{i(t', x), t_1 < t' \leq t_n\} \]

- **timselstd** Time selection standard deviation
  
  Normalize by n. For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \text{std}\{i(t', x), t_1 < t' \leq t_n\} \]

- **timselstd1** Time selection standard deviation (n-1)
  
  Normalize by (n-1). For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \text{std1}\{i(t', x), t_1 < t' \leq t_n\} \]

- **timselvar** Time selection variance
  
  Normalize by n. For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same selected time range it is:
  \[ o(t, x) = \text{var}\{i(t', x), t_1 < t' \leq t_n\} \]
**timselvar1**  
Time selection variance (n-1)  
Normalize by (n-1). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same selected time range it is:  
\[ o(t, x) = \text{var1}\{i(t', x), t_1 < t' \leq t_n\} \]

### Parameter
- **nsets** INTEGER  
Number of input timesteps for each output timestep  
- **noffset** INTEGER  
Number of input timesteps skipped before the first timestep range (optional)  
- **nskip** INTEGER  
Number of input timesteps skipped between timestep ranges (optional)

### Example
Assume an input dataset has monthly means over several years. To compute seasonal means from monthly means the first two months have to be skipped:

```
cdo timselmean,3,2 infile outfile
```

### 2.8.14. TIMSELPCTL - Time range percentile values

**Synopsis**

```
timselpctl p,nsets[,noffset[,nskip]] infile1 infile2 infile3 outfile
```

**Description**
This operator computes percentile values over a selected number of timesteps in `infile1`. The algorithm uses histograms with minimum and maximum bounds given in `infile2` and `infile3`, respectively. The default number of histogram bins is 101. The default can be overridden by setting the environment variable `CDO_PCTL_NBINS` to a different value. The files `infile2` and `infile3` should be the result of corresponding `timselmin` and `timselmax` operations, respectively. The time of `outfile` is determined by the time in the middle of all contributing timesteps of `infile1`. This can be change with the CDO option --timestat_date <first|middle|last>.

For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same selected time range it is:

\[ o(t, x) = \text{pth percentile}\{i(t', x), t_1 < t' \leq t_n\} \]

### Parameter
- **p** FLOAT  
Percentile number in 0, ..., 100  
- **nsets** INTEGER  
Number of input timesteps for each output timestep  
- **noffset** INTEGER  
Number of input timesteps skipped before the first timestep range (optional)  
- **nskip** INTEGER  
Number of input timesteps skipped between timestep ranges (optional)

### Environment
- **CDO_PCTL_NBINS** Sets the number of histogram bins. The default number is 101.
2.8.15. RUNSTAT - Running statistical values

Synopsis

<operator>,nts infile outfile

Description

This module computes running statistical values over a selected number of timesteps. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of a selected number of consecutive timesteps read from infile is written to outfile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>.

Operators

- **runmin**  Running minimum
  \[ o(t + (nts - 1)/2, x) = \min\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runmax**  Running maximum
  \[ o(t + (nts - 1)/2, x) = \max\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runrange**  Running range
  \[ o(t + (nts - 1)/2, x) = \range\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runsum**  Running sum
  \[ o(t + (nts - 1)/2, x) = \sum\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runmean**  Running mean
  \[ o(t + (nts - 1)/2, x) = \mean\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runavg**  Running average
  \[ o(t + (nts - 1)/2, x) = \avg\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runstd**  Running standard deviation
  Normalize by n.
  \[ o(t + (nts - 1)/2, x) = \std\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runstd1**  Running standard deviation (n-1)
  Normalize by (n-1).
  \[ o(t + (nts - 1)/2, x) = \std1\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runvar**  Running variance
  Normalize by n.
  \[ o(t + (nts - 1)/2, x) = \var\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]
- **runvar1**  Running variance (n-1)
  Normalize by (n-1).
  \[ o(t + (nts - 1)/2, x) = \var1\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]

Parameter

nts INTEGER Number of timesteps

Environment

CDO_TIMESTAT_DATE Sets the time stamp in outfile to the 'first', 'middle' or 'last' contributing timestep of infile.
Example

To compute the running mean over 9 timesteps use:

cdo runmean,9 infile outfile

2.8.16. RUNPCTL - Running percentile values

Synopsis

runpctl,p,nts infile outfile

Description

This module computes running percentiles over a selected number of timesteps in infile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>.

\[ o(t + (nts - 1)/2, x) = p\text{th percentile}\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x)\} \]

Parameter

- \( p \) FLOAT Percentile number in 0, ..., 100
- \( nts \) INTEGER Number of timesteps

Example

To compute the running 50th percentile (median) over 9 timesteps use:

cdo runpctl,50,9 infile outfile
2.8.17. TIMSTAT - Statistical values over all timesteps

Synopsis

<operator> infile outfile

Description

This module computes statistical values over all timesteps in infile. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of all timesteps read from infile is written to outfile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>.

Operators

- **timmin** Time minimum
  
  \[ o(1,x) = \min \{ i(t',x), t_1 < t' \leq t_n \} \]

- **timmax** Time maximum
  
  \[ o(1,x) = \max \{ i(t',x), t_1 < t' \leq t_n \} \]

- **timrange** Time range
  
  \[ o(1,x) = \text{range}\{ i(t',x), t_1 < t' \leq t_n \} \]

- **timsun** Time sum
  
  \[ o(1,x) = \text{sum}\{ i(t',x), t_1 < t' \leq t_n \} \]

- **timmean** Time mean
  
  \[ o(1,x) = \text{mean}\{ i(t',x), t_1 < t' \leq t_n \} \]

- **timavg** Time average
  
  \[ o(1,x) = \text{avg}\{ i(t',x), t_1 < t' \leq t_n \} \]

- **timstd** Time standard deviation
  
  Normalize by n.
  
  \[ o(1,x) = \text{std}\{ i(t',x), t_1 < t' \leq t_n \} \]

- **timstd1** Time standard deviation (n-1)
  
  Normalize by (n-1).
  
  \[ o(1,x) = \text{std1}\{ i(t',x), t_1 < t' \leq t_n \} \]

- **timvar** Time variance
  
  Normalize by n.
  
  \[ o(1,x) = \text{var}\{ i(t',x), t_1 < t' \leq t_n \} \]

- **timvar1** Time variance (n-1)
  
  Normalize by (n-1).
  
  \[ o(1,x) = \text{var1}\{ i(t',x), t_1 < t' \leq t_n \} \]

Example

To compute the mean over all input timesteps use:

```bash
cdo timmean infile outfile
```
2.8.18. TIMPCTL - Percentile values over all timesteps

Synopsis

timpctl,p infile1 infile2 infile3 outfile

Description

This operator computes percentiles over all timesteps in infile1. The algorithm uses histograms with minimum and maximum bounds given in infile2 and infile3, respectively. The default number of histogram bins is 101. The default can be overridden by defining the environment variable CDO_PCTL_NBINS. The files infile2 and infile3 should be the result of corresponding timmin and timmax operations, respectively. The time of outfile is determined by the time in the middle of all contributing timesteps of infile1. This can be change with the CDO option --timestat_date <first|middle|last>.

\[ o(1,x) = \text{pth percentile}\{i(t',x), t_1 < t' \leq t_n}\]

Parameter

\( p \) FLOAT Percentile number in 0, ..., 100

Environment

CDO_PCTL_NBINS Sets the number of histogram bins. The default number is 101.

Example

To compute the 90th percentile over all input timesteps use:

\[
\begin{align*}
\text{cdo timmin infile minfile} \\
\text{cdo timmax infile maxfile} \\
\text{cdo timpctl,90 infile minfile maxfile outfile}
\end{align*}
\]

Or shorter using operator piping:

\[
\begin{align*}
\text{cdo timpctl,90 infile -timmin infile -timmax infile outfile}
\end{align*}
\]
2.8.19. HOURSTAT - Hourly statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values over timesteps of the same hour. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of timesteps of the same hour is written to outfile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>.

Operators

- **hourmin**
  Hourly minimum
  For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \min \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **hourmax**
  Hourly maximum
  For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \max \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **hourrange**
  Hourly range
  For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \text{range} \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **hoursum**
  Hourly sum
  For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \text{sum} \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **hourmean**
  Hourly mean
  For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \text{mean} \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **houravg**
  Hourly average
  For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \text{avg} \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **hourstd**
  Hourly standard deviation
  Normalize by \( n \). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \text{std} \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **hourstd1**
  Hourly standard deviation (n-1)
  Normalize by (n-1). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \text{std1} \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **hourvar**
  Hourly variance
  Normalize by \( n \). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \text{var} \{ i(t', x), t_1 < t' \leq t_n \}
  \]

- **hourvar1**
  Hourly variance (n-1)
  Normalize by (n-1). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:
  \[
  o(t, x) = \text{var1} \{ i(t', x), t_1 < t' \leq t_n \}
  \]
Example

To compute the hourly mean of a time series use:

```
cdo hourmean infile outfile
```

2.8.20. HOURPCTL - Hourly percentile values

Synopsis

```
hourpctl,p infile1 infile2 infile3 outfile
```

Description

This operator computes percentiles over all timesteps of the same hour in `infile1`. The algorithm uses histograms with minimum and maximum bounds given in `infile2` and `infile3`, respectively. The default number of histogram bins is 101. The default can be overridden by defining the environment variable `CDO_PCTL_NBINS`. The files `infile2` and `infile3` should be the result of corresponding `hourmin` and `hourmax` operations, respectively. The time of `outfile` is determined by the time in the middle of all contributing timesteps of `infile1`. This can be change with the CDO option 

```cdo --timestat_date <first|middle|last>.
```

For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same hour it is:

\[
o(t, x) = p \text{th percentile}\{i(t', x), t_1 < t' \leq t_n\}
\]

Parameter

- \( p \) FLOAT Percentile number in 0, ..., 100

Environment

- `CDO_PCTL_NBINS` Sets the number of histogram bins. The default number is 101.

Example

To compute the hourly 90th percentile of a time series use:

```
cdo hourmin infile minfile
cdo hourmax infile maxfile
cdo hourpctl,90 infile minfile maxfile outfile
```

Or shorter using operator piping:

```
cdo hourpctl,90 infile -hourmin infile -hourmax infile outfile
```
2.8.21. DAYSTAT - Daily statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values over timesteps of the same day. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of timesteps of the same day is written to outfile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>.

Operators

daymin  Daily minimum
For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \min\{i(t', x), t_1 < t' \leq t_n\} \]
daymax  Daily maximum
For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \max\{i(t', x), t_1 < t' \leq t_n\} \]
dayrange Daily range
For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \text{range}\{i(t', x), t_1 < t' \leq t_n\} \]
daymean Daily mean
For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \text{mean}\{i(t', x), t_1 < t' \leq t_n\} \]
dayavg  Daily average
For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \text{avg}\{i(t', x), t_1 < t' \leq t_n\} \]
daystd  Daily standard deviation
Normalize by n. For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \text{std}\{i(t', x), t_1 < t' \leq t_n\} \]
daystd1 Daily standard deviation (n-1)
Normalize by (n-1). For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \text{std1}\{i(t', x), t_1 < t' \leq t_n\} \]
dayvar  Daily variance
Normalize by n. For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \text{var}\{i(t', x), t_1 < t' \leq t_n\} \]
dayvar1 Daily variance (n-1)
Normalize by (n-1). For every adjacent sequence $t_{-1}, ..., t_n$ of timesteps of the same day it is:
\[ o(t, x) = \text{var1}\{i(t', x), t_1 < t' \leq t_n\} \]
Example

To compute the daily mean of a time series use:

```
cdo daymean infile outfile
```

2.8.22. DAYPCTL - Daily percentile values

Synopsis

```
daypctl,p infile1 infile2 infile3 outfile
```

Description

This operator computes percentiles over all timesteps of the same day in `infile1`. The algorithm uses histograms with minimum and maximum bounds given in `infile2` and `infile3`, respectively. The default number of histogram bins is 101. The default can be overridden by defining the environment variable `CDO_PCTL_NBINS`. The files `infile2` and `infile3` should be the result of corresponding `daymin` and `daymax` operations, respectively. The time of `outfile` is determined by the time in the middle of all contributing timesteps of `infile1`. This can be change with the `CDO` option `--timestat_date <first|middle|last>`.

For every adjacent sequence `t_1,...,t_n` of timesteps of the same day it is:

\[
o(t,x) = p\text{th percentile}\{i(t',x), t_1 < t' \leq t_n\}
\]

Parameter

\[p\quad \text{FLOAT}\quad \text{Percentile number in 0, ..., 100}\]

Environment

\[\text{CDO_PCTL_NBINS}\quad \text{Sets the number of histogram bins. The default number is 101.}\]

Example

To compute the daily 90th percentile of a time series use:

```
cdo daymin infile minfile
```

```
cdo daymax infile maxfile
```

```
cdo daypctl,90 infile minfile maxfile outfile
```

Or shorter using operator piping:

```
cdo daypctl,90 infile -daymin infile -daymax infile outfile
```
2.8.23. MONSTAT - Monthly statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values over timesteps of the same month. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of timesteps of the same month is written to outfile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>.

Operators

monmin  Monthly minimum
For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \min \{ i(t', x), t_1 < t' \leq t_n \}
\]

monmax  Monthly maximum
For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \max \{ i(t', x), t_1 < t' \leq t_n \}
\]

monrange Monthly range
For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \text{range} \{ i(t', x), t_1 < t' \leq t_n \}
\]

monsum  Monthly sum
For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \sum \{ i(t', x), t_1 < t' \leq t_n \}
\]

monmean Monthly mean
For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \text{mean} \{ i(t', x), t_1 < t' \leq t_n \}
\]

monavg  Monthly average
For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \text{avg} \{ i(t', x), t_1 < t' \leq t_n \}
\]

monstd  Monthly standard deviation
Normalize by \( n \). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \text{std} \{ i(t', x), t_1 < t' \leq t_n \}
\]

monstd1 Monthly standard deviation (n-1)
Normalize by (n-1). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \text{std1} \{ i(t', x), t_1 < t' \leq t_n \}
\]

monvar  Monthly variance
Normalize by \( n \). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \text{var} \{ i(t', x), t_1 < t' \leq t_n \}
\]

monvar1 Monthly variance (n-1)
Normalize by (n-1). For every adjacent sequence \( t_1, \ldots, t_n \) of timesteps of the same month it is:
\[
o(t, x) = \text{var1} \{ i(t', x), t_1 < t' \leq t_n \}
\]
Example

To compute the monthly mean of a time series use:

```
cdo monmean infile outfile
```

2.8.24. MONPCTL - Monthly percentile values

Synopsis

```
monpctl,p infile1 infile2 infile3 outfile
```

Description

This operator computes percentiles over all timesteps of the same month in `infile1`. The algorithm uses histograms with minimum and maximum bounds given in `infile2` and `infile3`, respectively. The default number of histogram bins is 101. The default can be overridden by defining the environment variable `CDO_PCTL_NBINS`. The files `infile2` and `infile3` should be the result of corresponding `monmin` and `monmax` operations, respectively. The time of `outfile` is determined by the time in the middle of all contributing timesteps of `infile1`. This can be change with the `CDO` option `--timestat_date <first|middle|last>`.

For every adjacent sequence `t_1,...,t_n` of timesteps of the same month it is:

```
o(t,x) = pth percentile\{i(t',x), t_1 < t' \leq t_n\}
```

Parameter

```
p  FLOAT  Percentile number in 0, ..., 100
```

Environment

```
CDO_PCTL_NBINS  Sets the number of histogram bins. The default number is 101.
```

Example

To compute the monthly 90th percentile of a time series use:

```
cdo monmin infile minfile
```

```
cdo monmax infile maxfile
```

```
cdo monpctl,90 infile minfile maxfile outfile
```

Or shorter using operator piping:

```
cdo monpctl,90 infile -monmin infile -monmax infile outfile
```
2.8.25. YEARMONSTAT - Yearly mean from monthly data

Synopsis

\texttt{yearmonmean infile outfile}

Description

This operator computes the yearly mean of a monthly time series. Each month is weighted with the number of days per month. The time of \texttt{outfile} is determined by the time in the middle of all contributing timesteps of \texttt{infile}.

For every adjacent sequence $t_1, ..., t_n$ of timesteps of the same year it is:

\[ o(t, x) = \text{mean}\{i(t', x), t_1 < t' \leq t_n\} \]

Environment

\texttt{CDO\_TIMESTAT\_DATE} \quad Sets the date information in \texttt{outfile} to the 'first', 'middle' or 'last' contributing timestep of \texttt{infile}.

Example

To compute the yearly mean of a monthly time series use:

\begin{verbatim}
 cdo yearmonmean infile outfile
\end{verbatim}
2.8.26. YEARSTAT - Yearly statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values over timesteps of the same year. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of timesteps of the same year is written to outfile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>.

</tr>
</tbody>
</table>
yearvar1 Yearly variance \((n-1)\)
Normalize by \((n-1)\). For every adjacent sequence \(t_1, \ldots, t_n\) of timesteps of the same year it is:

\[ o(t,x) = \text{var1}\{i(t',x), t_1 < t' \leq t_n\} \]

**Note**

The operators yearmean and yearavg compute only arithmetical means!

**Example**

To compute the yearly mean of a time series use:

```
cdo yearmean infile outfile
```

To compute the yearly mean from the correct weighted monthly mean use:

```
cdo yearmonmean infile outfile
```

### 2.8.27. YEARPCTL - Yearly percentile values

**Synopsis**

```
yearpctl,p infile1 infile2 infile3 outfile
```

**Description**

This operator computes percentiles over all timesteps of the same year in `infile1`. The algorithm uses histograms with minimum and maximum bounds given in `infile2` and `infile3`, respectively. The default number of histogram bins is 101. The default can be overridden by defining the environment variable `CDO_PCTL_NBINS`. The files `infile2` and `infile3` should be the result of corresponding `yearmin` and `yearmax` operations, respectively. The time of `outfile` is determined by the time in the middle of all contributing timesteps of `infile1`. This can be change with the `CDO` option `--timestat_date <first|middle|last>`. For every adjacent sequence \(t_1, \ldots, t_n\) of timesteps of the same year it is:

\[ o(t,x) = p\text{th percentile}\{i(t',x), t_1 < t' \leq t_n\} \]

**Parameter**

- \( p \quad \text{FLOAT} \) Percentile number in 0, ..., 100

**Environment**

- `CDO_PCTL_NBINS` Sets the number of histogram bins. The default number is 101.

**Example**

To compute the yearly 90th percentile of a time series use:

```
cdo yearmin infile minfile
cdo yearmax infile maxfile
cdo yearpctl,90 infile minfile maxfile outfile
```

Or shorter using operator piping:

```
cdo yearpctl,90 infile -yearmin infile -yearmax infile outfile
```
2.8.28. SEASSTAT - Seasonal statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values over timesteps of the same season. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of timesteps of the same season is written to outfile. The time of outfile is determined by the time in the middle of all contributing timesteps of infile. This can be change with the CDO option --timestat_date <first|middle|last>. Be careful about the first and the last output timestep, they may be incorrect values if the seasons have incomplete timesteps.

Operators

seasmin  Seasonal minimum
For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \min\{i(t', x), t_1 < t' \leq t_n\}
\]

seasmax  Seasonal maximum
For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \max\{i(t', x), t_1 < t' \leq t_n\}
\]

seasrange  Seasonal range
For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \text{range}\{i(t', x), t_1 < t' \leq t_n\}
\]

seassum  Seasonal sum
For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \text{sum}\{i(t', x), t_1 < t' \leq t_n\}
\]

seasmean  Seasonal mean
For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \text{mean}\{i(t', x), t_1 < t' \leq t_n\}
\]

seasavg  Seasonal average
For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \text{avg}\{i(t', x), t_1 < t' \leq t_n\}
\]

seasstd  Seasonal standard deviation Normalize by n. For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \text{std}\{i(t', x), t_1 < t' \leq t_n\}
\]

seasstd1  Seasonal standard deviation (n-1) Normalize by (n-1). For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \text{std1}\{i(t', x), t_1 < t' \leq t_n\}
\]

seasvar  Seasonal variance Normalize by n. For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \text{var}\{i(t', x), t_1 < t' \leq t_n\}
\]

seasvar1  Seasonal variance (n-1) Normalize by (n-1). For every adjacent sequence \(t_1, ..., t_n\) of timesteps of the same season it is:
\[
o(t, x) = \text{var1}\{i(t', x), t_1 < t' \leq t_n\}
\]
Example

To compute the seasonal mean of a time series use:

```
cdo seasmean infile outfile
```

2.8.29. SEASPCTL - Seasonal percentile values

Synopsis

```
seaspctl,p infile1 infile2 infile3 outfile
```

Description

This operator computes percentiles over all timesteps in `infile1` of the same season. The algorithm uses histograms with minimum and maximum bounds given in `infile2` and `infile3`, respectively. The default number of histogram bins is 101. The default can be overridden by defining the environment variable `CDO_PCTL_NBINS`. The files `infile2` and `infile3` should be the result of corresponding `seasmin` and `seasmax` operations, respectively. The time of `outfile` is determined by the time in the middle of all contributing timesteps of `infile1`. This can be change with the `CDO` option `--timestat_date<first|middle|last>`.

For every adjacent sequence `t_1, ..., t_n` of timesteps of the same season it is:

\[ o(t, x) = p \text{ th percentile}\{i(t', x), t_1 < t' \leq t_n}\]  

Parameter

\[ p \text{ FLOAT} \]  
Percentile number in 0, ..., 100

Environment

\[ \text{CDO_PCTL_NBINS} \]  
Sets the number of histogram bins. The default number is 101.

Example

To compute the seasonal 90th percentile of a time series use:

```
cdo seasmin infile minfile
cdo seasmax infile maxfile
cdo seaspctl,90 infile minfile maxfile outfile
```

Or shorter using operator piping:

```
cdo seaspctl,90 infile -seasmin infile -seasmax infile outfile
```
2.8.30. YHOURSTAT - Multi-year hourly statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values of each hour and day of year. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of each hour and day of year in infile is written to outfile. The date information in an output field is the date of the last contributing input field.

Operators

**yhourmin** Multi-year hourly minimum
\[ o(0001, x) = \min\{i(t, x), day(i(t)) = 0001\} \]
\[ \vdots \]
\[ o(8784, x) = \min\{i(t, x), day(i(t)) = 8784\} \]

**yhourmax** Multi-year hourly maximum
\[ o(0001, x) = \max\{i(t, x), day(i(t)) = 0001\} \]
\[ \vdots \]
\[ o(8784, x) = \max\{i(t, x), day(i(t)) = 8784\} \]

**yhourrange** Multi-year hourly range
\[ o(0001, x) = \text{range}\{i(t, x), day(i(t)) = 0001\} \]
\[ \vdots \]
\[ o(8784, x) = \text{range}\{i(t, x), day(i(t)) = 8784\} \]

**yhoursum** Multi-year hourly sum
\[ o(0001, x) = \sum\{i(t, x), day(i(t)) = 0001\} \]
\[ \vdots \]
\[ o(8784, x) = \sum\{i(t, x), day(i(t)) = 8784\} \]

**yhourmean** Multi-year hourly mean
\[ o(0001, x) = \text{mean}\{i(t, x), day(i(t)) = 0001\} \]
\[ \vdots \]
\[ o(8784, x) = \text{mean}\{i(t, x), day(i(t)) = 8784\} \]

**yhouravg** Multi-year hourly average
\[ o(0001, x) = \text{avg}\{i(t, x), day(i(t)) = 0001\} \]
\[ \vdots \]
\[ o(8784, x) = \text{avg}\{i(t, x), day(i(t)) = 8784\} \]

**yhourstd** Multi-year hourly standard deviation
Normalize by \( n \).
\[ o(0001, x) = \text{std}\{i(t, x), day(i(t)) = 0001\} \]
\[ \vdots \]
\[ o(8784, x) = \text{std}\{i(t, x), day(i(t)) = 8784\} \]

**yhourstd1** Multi-year hourly standard deviation (\( n-1 \))
Normalize by \( (n-1) \).
\[ o(0001, x) = \text{std1}\{i(t, x), \text{day}(i(t)) = 0001\} \]
\[ o(8784, x) = \text{std1}\{i(t, x), \text{day}(i(t)) = 8784\} \]

**yhourvar**

Multi-year hourly variance
Normalize by n.
\[ o(0001, x) = \text{var}\{i(t, x), \text{day}(i(t)) = 0001\} \]
\[ o(8784, x) = \text{var}\{i(t, x), \text{day}(i(t)) = 8784\} \]

**yhourvar1**

Multi-year hourly variance (n-1)
Normalize by (n-1).
\[ o(0001, x) = \text{var1}\{i(t, x), \text{day}(i(t)) = 0001\} \]
\[ o(8784, x) = \text{var1}\{i(t, x), \text{day}(i(t)) = 8784\} \]
2.8.31. DHOURSTAT - Multi-day hourly statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values of each hour of day. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of each hour of day in infile is written to outfile. The date information in an output field is the date of the last contributing input field.

Operators

- **dhourmin** Multi-day hourly minimum
  
  \[
  o(01, x) = \min\{i(t, x), \text{day}(i(t)) = 01\} \\
  \vdots \\
  o(24, x) = \min\{i(t, x), \text{day}(i(t)) = 24\}
  \]

- **dhourmax** Multi-day hourly maximum
  
  \[
  o(01, x) = \max\{i(t, x), \text{day}(i(t)) = 01\} \\
  \vdots \\
  o(24, x) = \max\{i(t, x), \text{day}(i(t)) = 24\}
  \]

- **dhourrange** Multi-day hourly range
  
  \[
  o(01, x) = \text{range}\{i(t, x), \text{day}(i(t)) = 01\} \\
  \vdots \\
  o(24, x) = \text{range}\{i(t, x), \text{day}(i(t)) = 24\}
  \]

- **dhoursum** Multi-day hourly sum
  
  \[
  o(01, x) = \sum\{i(t, x), \text{day}(i(t)) = 01\} \\
  \vdots \\
  o(24, x) = \sum\{i(t, x), \text{day}(i(t)) = 24\}
  \]

- **dhourmean** Multi-day hourly mean
  
  \[
  o(01, x) = \text{mean}\{i(t, x), \text{day}(i(t)) = 01\} \\
  \vdots \\
  o(24, x) = \text{mean}\{i(t, x), \text{day}(i(t)) = 24\}
  \]

- **dhouravg** Multi-day hourly average
  
  \[
  o(01, x) = \text{avg}\{i(t, x), \text{day}(i(t)) = 01\} \\
  \vdots \\
  o(24, x) = \text{avg}\{i(t, x), \text{day}(i(t)) = 24\}
  \]

- **dhourstd** Multi-day hourly standard deviation
  Normalize by n.
  
  \[
  o(01, x) = \text{std}\{i(t, x), \text{day}(i(t)) = 01\} \\
  \vdots \\
  o(24, x) = \text{std}\{i(t, x), \text{day}(i(t)) = 24\}
  \]

- **dhourstd1** Multi-day hourly standard deviation (n-1)
  Normalize by (n-1).
\[ o(01, x) = \text{std1}\{i(t, x), \text{day}(i(t)) = 01\} \]
\[ o(24, x) = \text{std1}\{i(t, x), \text{day}(i(t)) = 24\} \]

**dhourvar**

Multi-day hourly variance
Normalize by \( n \).
\[ o(01, x) = \text{var}\{i(t, x), \text{day}(i(t)) = 01\} \]
\[ o(24, x) = \text{var}\{i(t, x), \text{day}(i(t)) = 24\} \]

**dhourvar1**

Multi-day hourly variance (n-1)
Normalize by (n-1).
\[ o(01, x) = \text{var1}\{i(t, x), \text{day}(i(t)) = 01\} \]
\[ o(24, x) = \text{var1}\{i(t, x), \text{day}(i(t)) = 24\} \]
2.8.32. YDAYSTAT - Multi-year daily statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values of each day of year. Depending on the chosen operator the minimum, maximum, range, sum, average, variance or standard deviation of each day of year in infile is written to outfile. The date information in an output field is the date of the last contributing input field.

Operators

**ydaymin**
Multi-year daily minimum

\[ o(001, x) = \min\{i(t, x), \text{day}(i(t)) = 001\} \]

\[ o(366, x) = \min\{i(t, x), \text{day}(i(t)) = 366\} \]

**ydaymax**
Multi-year daily maximum

\[ o(001, x) = \max\{i(t, x), \text{day}(i(t)) = 001\} \]

\[ o(366, x) = \max\{i(t, x), \text{day}(i(t)) = 366\} \]

**ydayrange**
Multi-year daily range

\[ o(001, x) = \text{range}\{i(t, x), \text{day}(i(t)) = 001\} \]

\[ o(366, x) = \text{range}\{i(t, x), \text{day}(i(t)) = 366\} \]

**ydaysum**
Multi-year daily sum

\[ o(001, x) = \text{sum}\{i(t, x), \text{day}(i(t)) = 001\} \]

\[ o(366, x) = \text{sum}\{i(t, x), \text{day}(i(t)) = 366\} \]

**ydaymean**
Multi-year daily mean

\[ o(001, x) = \text{mean}\{i(t, x), \text{day}(i(t)) = 001\} \]

\[ o(366, x) = \text{mean}\{i(t, x), \text{day}(i(t)) = 366\} \]

**ydayavg**
Multi-year daily average

\[ o(001, x) = \text{avg}\{i(t, x), \text{day}(i(t)) = 001\} \]

\[ o(366, x) = \text{avg}\{i(t, x), \text{day}(i(t)) = 366\} \]

**ydaystd**
Multi-year daily standard deviation
Normalize by \( n \).

\[ o(001, x) = \text{std}\{i(t, x), \text{day}(i(t)) = 001\} \]

\[ o(366, x) = \text{std}\{i(t, x), \text{day}(i(t)) = 366\} \]

**ydaystd1**
Multi-year daily standard deviation (n-1)
Normalize by (n-1).
$o(001, x) = \text{std1}\{i(t, x), \text{day}(i(t)) = 001\}$

$\vdots$

$o(366, x) = \text{std1}\{i(t, x), \text{day}(i(t)) = 366\}$

**ydayvar**

Multi-year daily variance

Normalize by $n$.

$\begin{align*}
    o(001, x) &= \text{var}\{i(t, x), \text{day}(i(t)) = 001\} \\
    \vdots \\
    o(366, x) &= \text{var}\{i(t, x), \text{day}(i(t)) = 366\}
\end{align*}$

**ydayvar1**

Multi-year daily variance (n-1)

Normalize by $(n-1)$.

$\begin{align*}
    o(001, x) &= \text{var1}\{i(t, x), \text{day}(i(t)) = 001\} \\
    \vdots \\
    o(366, x) &= \text{var1}\{i(t, x), \text{day}(i(t)) = 366\}
\end{align*}$

**Example**

To compute the daily mean over all input years use:

```
cdo ydaymean infile outfile
```
2.8.33. **YDYPCTL - Multi-year daily percentile values**

**Synopsis**

\[ \text{ydaypctl,} p \text{ infile1 infile2 infile3 outfile} \]

**Description**

This operator writes a certain percentile of each day of year in `infile1` to `outfile`. The algorithm uses histograms with minimum and maximum bounds given in `infile2` and `infile3`, respectively. The default number of histogram bins is 101. The default can be overridden by setting the environment variable `CDO_PCTL_NBINS` to a different value. The files `infile2` and `infile3` should be the result of corresponding `ydaymin` and `ydaymax` operations, respectively. The date information in an output field is the date of the last contributing input field.

\[
\begin{align*}
    o(001, x) &= \text{pth percentile}\{i(t, x), \text{day}(i(t)) = 001\} \\
    \vdots \nonumber \\
    o(366, x) &= \text{pth percentile}\{i(t, x), \text{day}(i(t)) = 366\}
\end{align*}
\]

**Parameter**

\[ p \quad \text{FLOAT} \quad \text{Percentile number in 0, ..., 100} \]

**Environment**

`CDO_PCTL_NBINS`  Sets the number of histogram bins. The default number is 101.

**Example**

To compute the daily 90th percentile over all input years use:

```
cdo ydaymin infile minfile
ncdo ydaymax infile maxfile
ncdo ydypctl,90 infile minfile maxfile outfile
```

Or shorter using operator piping:

```
cdo ydypctl,90 infile -ydaymin infile -ydaymax infile outfile
```
2.8.34. YMONSTAT - Multi-year monthly statistical values

Synopsis

<operator> infile outfile

Description

This module computes statistical values of each month of year. Depending on the chosen operator
the minimum, maximum, range, sum, average, variance or standard deviation of each month of year
in infile is written to outfile. The date information in an output field is the date of the last con-
tributing input field. This can be change with the CDO option --timestat_date <first>middle>last>.

\[ o(1, x) = \text{std1}\{i(t, x), \text{month}(i(t)) = 12, 01, 02\} \]
\[ o(2, x) = \text{std1}\{i(t, x), \text{month}(i(t)) = 03, 04, 05\} \]
\[ o(3, x) = \text{std1}\{i(t, x), \text{month}(i(t)) = 06, 07, 08\} \]
\[ o(4, x) = \text{std1}\{i(t, x), \text{month}(i(t)) = 09, 10, 11\} \]

**yseasvar**  
Multi-year seasonal variance

\[ o(1, x) = \text{var}\{i(t, x), \text{month}(i(t)) = 12, 01, 02\} \]
\[ o(2, x) = \text{var}\{i(t, x), \text{month}(i(t)) = 03, 04, 05\} \]
\[ o(3, x) = \text{var}\{i(t, x), \text{month}(i(t)) = 06, 07, 08\} \]
\[ o(4, x) = \text{var}\{i(t, x), \text{month}(i(t)) = 09, 10, 11\} \]

**yseasvar1**  
Multi-year seasonal variance \((n-1)\)

\[ o(1, x) = \text{var1}\{i(t, x), \text{month}(i(t)) = 12, 01, 02\} \]
\[ o(2, x) = \text{var1}\{i(t, x), \text{month}(i(t)) = 03, 04, 05\} \]
\[ o(3, x) = \text{var1}\{i(t, x), \text{month}(i(t)) = 06, 07, 08\} \]
\[ o(4, x) = \text{var1}\{i(t, x), \text{month}(i(t)) = 09, 10, 11\} \]

**Example**

To compute the seasonal mean over all input years use:

```
cdo yseasmean infile outfile
```
2.8.37. YSEASPCTL - Multi-year seasonal percentile values

Synopsis

yseaspctl\texttt{,p infile1 infile2 infile3 outfile}

Description

This operator writes a certain percentile of each season in infile1 to outfile. The algorithm uses histograms with minimum and maximum bounds given in infile2 and infile3, respectively. The default number of histogram bins is 101. The default can be overridden by setting the environment variable \texttt{CDO\_PCTL\_NBINS} to a different value. The files infile2 and infile3 should be the result of corresponding yseasmin and yseasmax operations, respectively. The date information in an output field is the date of the last contributing input field.

\[
o(1, x) = \text{pth percentile}\left\{i(t, x), \text{month}(i(t)) = 12, 01, 02\right\}
\]
\[
o(2, x) = \text{pth percentile}\left\{i(t, x), \text{month}(i(t)) = 03, 04, 05\right\}
\]
\[
o(3, x) = \text{pth percentile}\left\{i(t, x), \text{month}(i(t)) = 06, 07, 08\right\}
\]
\[
o(4, x) = \text{pth percentile}\left\{i(t, x), \text{month}(i(t)) = 09, 10, 11\right\}
\]

Parameter

\begin{itemize}
  \item \texttt{p}\quad\text{FLOAT}\quad\text{Percentile number in 0, ..., 100}
\end{itemize}

Environment

\begin{itemize}
  \item \texttt{CDO\_PCTL\_NBINS}\quad\text{Sets the number of histogram bins. The default number is 101.}
\end{itemize}

Example

To compute the seasonal 90th percentile over all input years use:

\begin{verbatim}
cdo yseasmin infile minfile
cdo yseasmax infile maxfile
cdo yseaspctl,90 infile minfile maxfile outfile
\end{verbatim}

Or shorter using operator piping:

\begin{verbatim}
cdo yseaspctl,90 infile -yseasmin infile -yseasmax infile outfile
\end{verbatim}
2.8.38. YDRUNSTAT - Multi-year daily running statistical values

Synopsis

<operator>.nts infile outfile

Description

This module writes running statistical values for each day of year in infile to outfile. Depending on the chosen operator, the minimum, maximum, sum, average, variance or standard deviation of all timesteps in running windows of which the medium timestep corresponds to a certain day of year is computed. The date information in an output field is the date of the timestep in the middle of the last contributing running window. Note that the operator have to be applied to a continuous time series of daily measurements in order to yield physically meaningful results. Also note that the output time series begins \((nts-1)/2\) timesteps after the first timestep of the input time series and ends \((nts-1)/2\) timesteps before the last one. For input data which are complete but not continuous, such as time series of daily measurements for the same month or season within different years, the operator yields physically meaningful results only if the input time series does include the \((nts-1)/2\) days before and after each period of interest.

Operators

- **ydrunmin** Multi-year daily running minimum
  
  \[
  a(001, x) = \min \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001\} \\
  \vdots
  \\
  a(366, x) = \min \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366\}
  \]

- **ydrunmax** Multi-year daily running maximum
  
  \[
  a(001, x) = \max \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001\} \\
  \vdots
  \\
  a(366, x) = \max \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366\}
  \]

- **ydrunsum** Multi-year daily running sum
  
  \[
  a(001, x) = \sum \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001\} \\
  \vdots
  \\
  a(366, x) = \sum \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366\}
  \]

- **ydrunmean** Multi-year daily running mean
  
  \[
  a(001, x) = \text{mean} \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001\} \\
  \vdots
  \\
  a(366, x) = \text{mean} \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366\}
  \]

- **ydrunavg** Multi-year daily running average
  
  \[
  a(001, x) = \text{avg} \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001\} \\
  \vdots
  \\
  a(366, x) = \text{avg} \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366\}
  \]

- **ydrunstd** Multi-year daily running standard deviation
  
  Normalize by \(n\).
  
  \[
  a(001, x) = \text{std} \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001\} \\
  \vdots
  \\
  a(366, x) = \text{std} \{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366\}
  \]
**ydrunstd1**  Multi-year daily running standard deviation (n-1)  
Normalize by (n-1).

\[
o(001, x) = \text{std1}\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001}\]
\[
...\]
\[
o(366, x) = \text{std1}\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366}\]

**ydrunvar**  Multi-year daily running variance  
Normalize by n.

\[
o(001, x) = \text{var}\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001}\]
\[
...\]
\[
o(366, x) = \text{var}\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366}\]

**ydrunvar1**  Multi-year daily running variance (n-1)  
Normalize by (n-1).

\[
o(001, x) = \text{var1}\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 001}\]
\[
...\]
\[
o(366, x) = \text{var1}\{i(t, x), i(t + 1, x), ..., i(t + nts - 1, x); \text{day}[i(t + (nts - 1)/2)] = 366}\]

### Parameter

\[
n_{ts} \quad \text{INTEGER} \quad \text{Number of timesteps}\]

### Example

Assume the input data provide a continuous time series of daily measurements. To compute the running multi-year daily mean over all input timesteps for a running window of five days use:

```
cdo ydrunmean,5 infile outfile
```

Note that except for the standard deviation the results of the operators in this module are equivalent to a composition of corresponding operators from the YDAYSTAT and RUNSTAT modules. For instance, the above command yields the same result as:

```
cdo ydaymean -runmean,5 infile outfile
```
2.8.39. YDRUNPCTL - Multi-year daily running percentile values

Synopsis

```
ydrunpctl,p,nts infile1 infile2 infile3 outfile
```

Description

This operator writes running percentile values for each day of year in `infile1` to `outfile`. A certain percentile is computed for all timesteps in running windows of which the medium timestep corresponds to a certain day of year. The algorithm uses histograms with minimum and maximum bounds given in `infile2` and `infile3`, respectively. The default number of histogram bins is 101. The default can be overridden by setting the environment variable `CDO_PCTL_NBINS` to a different value. The files `infile2` and `infile3` should be the result of corresponding `ydrunmin` and `ydrunmax` operations, respectively. The date information in an output field is the date of the timestep in the middle of the last contributing running window. Note that the operator have to be applied to a continuous time series of daily measurements in order to yield physically meaningful results. Also note that the output time series begins `(nts-1)/2` timesteps after the first timestep of the input time series and ends `(nts-1)/2` timesteps before the last. For input data which are complete but not continuous, such as time series of daily measurements for the same month or season within different years, the operator only yields physically meaningful results if the input time series does include the `(nts-1)/2` days before and after each period of interest.

\[
o(001, x) = \text{pth percentile}\{ i(t,x), i(t+1,x), ..., i(t+nts-1,x); \text{day}[(i(t+(nts-1)/2)] = 001 \} \\
\vdots
\]

\[
o(366, x) = \text{pth percentile}\{ i(t,x), i(t+1,x), ..., i(t+nts-1,x); \text{day}[(i(t+(nts-1)/2)] = 366 \}
\]

Parameter

- `p`  FLOAT  Percentile number in 0, ..., 100
- `nts`  INTEGER  Number of timesteps

Environment

- `CDO_PCTL_NBINS`  Sets the number of histogram bins. The default number is 101.

Example

Assume the input data provide a continuous time series of daily measurements. To compute the running multi-year daily 90th percentile over all input timesteps for a running window of five days use:

```
cdo ydrunmin,5 infile minfile 
cdo ydrunmax,5 infile maxfile 
cdo ydrunpctl,90,5 infile minfile maxfile outfile
```

Or shorter using operator piping:

```
cdo ydrunpctl,90,5 infile -ydrunmin infile -ydrunmax infile outfile
```
2.9. Correlation and co.

This sections contains modules for correlation and co. in grid space and over time.
In this section the abbreviations as in the following table are used:

<table>
<thead>
<tr>
<th>Covariance</th>
<th>$n^{-1} \sum_{i=1}^{n} (x_i - \bar{x})(y_i - \bar{y})$</th>
</tr>
</thead>
<tbody>
<tr>
<td>covar weighted by</td>
<td>$(\sum_{j=1}^{n} w_j)^{-1} \left( \sum_{i=1}^{n} w_i \left( x_i - \left( \sum_{j=1}^{n} w_j \right)^{-1} \sum_{j=1}^{n} w_j x_j \right) \right) \left( y_i - \left( \sum_{j=1}^{n} w_j \right)^{-1} \sum_{j=1}^{n} w_j y_j \right)$</td>
</tr>
</tbody>
</table>

Here is a short overview of all operators in this section:

- **fldcor**: Correlation in grid space
- **timcor**: Correlation over time
- **fldcovar**: Covariance in grid space
- **timcovar**: Covariance over time
2.9.1. FLDCOR - Correlation in grid space

Synopsis

fldcor infile1 infile2 outfile

Description

The correlation coefficient is a quantity that gives the quality of a least squares fitting to the original data. This operator correlates all gridpoints of two fields for each timestep. With

\[ S(t) = \{ x, i_1(t, x) \neq missval \land i_2(t, x) \neq missval \} \]

it is

\[
\rho(t, 1) = \frac{\sum_{x \in S(t)} i_1(t, x) i_2(t, x) w(x) - \overline{i_1(t, x)} \overline{i_2(t, x)} \sum_{x \in S(t)} w(x)}{\sqrt{\left( \sum_{x \in S(t)} i_1(t, x)^2 w(x) - \overline{i_1(t, x)}^2 \sum_{x \in S(t)} w(x) \right) \left( \sum_{x \in S(t)} i_2(t, x)^2 w(x) - \overline{i_2(t, x)}^2 \sum_{x \in S(t)} w(x) \right)}}
\]

where \( w(x) \) are the area weights obtained by the input streams. For every timestep \( t \) only those field elements \( x \) belong to the sample, which have \( i_1(t, x) \neq missval \) and \( i_2(t, x) \neq missval \).

2.9.2. TIMCOR - Correlation over time

Synopsis

timcor infile1 infile2 outfile

Description

The correlation coefficient is a quantity that gives the quality of a least squares fitting to the original data. This operator correlates each gridpoint of two fields over all timesteps. With

\[ S(x) = \{ t, i_1(t, x) \neq missval \land i_2(t, x) \neq missval \} \]

it is

\[
\rho(1, x) = \frac{\sum_{t \in S(x)} i_1(t, x) i_2(t, x) - n \overline{i_1(t, x)} \overline{i_2(t, x)}}{\sqrt{\left( \sum_{t \in S(x)} i_1(t, x)^2 - n \overline{i_1(t, x)}^2 \right) \left( \sum_{t \in S(x)} i_2(t, x)^2 - n \overline{i_2(t, x)}^2 \right)}}
\]

For every gridpoint \( x \) only those timesteps \( t \) belong to the sample, which have \( i_1(t, x) \neq missval \) and \( i_2(t, x) \neq missval \).
2.9.3. FLDCOVAR - Covariance in grid space

Synopsis

fldcovar infile1 infile2 outfile

Description

This operator calculates the covariance of two fields over all gridpoints for each timestep. With

\[ S(t) = \{ x, i_1(t, x) \neq missval \land i_2(t, x) \neq missval \} \]

it is

\[
O(t, 1) = \left( \sum_{x \in S(t)} w(x) \right)^{-1} \sum_{x \in S(t)} w(x) \left( i_1(t, x) - \frac{\sum_{x \in S(t)} w(x) i_1(t, x)}{\sum_{x \in S(t)} w(x)} \right) \left( i_2(t, x) - \frac{\sum_{x \in S(t)} w(x) i_2(t, x)}{\sum_{x \in S(t)} w(x)} \right)
\]

where \( w(x) \) are the area weights obtained by the input streams. For every timestep \( t \) only those field elements \( x \) belong to the sample, which have \( i_1(t, x) \neq missval \) and \( i_2(t, x) \neq missval \).

2.9.4. TIMCOVAR - Covariance over time

Synopsis

timcovar infile1 infile2 outfile

Description

This operator calculates the covariance of two fields at each gridpoint over all timesteps. With

\[ S(x) = \{ t, i_1(t, x) \neq missval \land i_2(t, x) \neq missval \} \]

it is

\[
O(1, x) = n^{-1} \sum_{t \in S(x)} \left( i_1(t, x) - \overline{i_1(t, x)} \right) \left( i_2(t, x) - \overline{i_2(t, x)} \right)
\]

For every gridpoint \( x \) only those timesteps \( t \) belong to the sample, which have \( i_1(t, x) \neq missval \) and \( i_2(t, x) \neq missval \).
2.10. Regression

This section contains modules for linear regression of time series.

Here is a short overview of all operators in this section:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>regres</td>
<td>Regression</td>
</tr>
<tr>
<td>detrend</td>
<td>Detrend</td>
</tr>
<tr>
<td>trend</td>
<td>Trend</td>
</tr>
<tr>
<td>addtrend</td>
<td>Add trend</td>
</tr>
<tr>
<td>subtrend</td>
<td>Subtract trend</td>
</tr>
</tbody>
</table>
### 2.10.1. REGRES - Regression

#### Synopsis

\[ \text{regres}[\text{equal}] \text{ infile outfile} \]

#### Description

The values of the input file `infile` are assumed to be distributed as \( N(a + bt, \sigma^2) \) with unknown \( a \), \( b \) and \( \sigma^2 \). This operator estimates the parameter \( b \). For every field element \( x \) only those timesteps \( t \) belong to the sample \( S(x) \), which have \( i(t, x) \neq \text{miss} \). It is

\[
o(1, x) = \sum_{t \in S(x)} \left( i(t, x) - \frac{1}{\#S(x)} \sum_{t' \in S(x)} i(t', x) \right) \left( t - \frac{1}{\#S(x)} \sum_{t' \in S(x)} t' \right) 
\]

\[
\sum_{t \in S(x)} \left( t - \frac{1}{\#S(x)} \sum_{t' \in S(x)} t' \right)^2
\]

It is assumed that all timesteps are equidistant, if this is not the case set the parameter `equal=false`.

#### Parameter

`equal`  BOOL  Set to false for unequal distributed timesteps (default: true)

### 2.10.2. DETREND - Detrend time series

#### Synopsis

\[ \text{detrend}[\text{equal}] \text{ infile outfile} \]

#### Description

Every time series in `infile` is linearly detrended. For every field element \( x \) only those timesteps \( t \) belong to the sample \( S(x) \), which have \( i(t, x) \neq \text{miss} \). It is assumed that all timesteps are equidistant, if this is not the case set the parameter `equal=false`. With

\[
a(x) = \frac{1}{\#S(x)} \sum_{t \in S(x)} i(t, x) - b(x) \left( \frac{1}{\#S(x)} \sum_{t \in S(x)} t \right)
\]

and

\[
b(x) = \frac{\sum_{t \in S(x)} \left( i(t, x) - \frac{1}{\#S(x)} \sum_{t' \in S(x)} i(t', x) \right) \left( t - \frac{1}{\#S(x)} \sum_{t' \in S(x)} t' \right)}{\sum_{t \in S(x)} \left( t - \frac{1}{\#S(x)} \sum_{t' \in S(x)} t' \right)^2}
\]

it is

\[
o(t, x) = i(t, x) - (a(x) + b(x)t)
\]

#### Parameter

`equal`  BOOL  Set to false for unequal distributed timesteps (default: true)
Note

This operator has to keep the fields of all timesteps concurrently in the memory. If not enough memory is available use the operators trend and subtrend.

Example

To detrend the data in infile and to store the detrended data in outfile use:

\[
\text{cdo detrend infile outfile}
\]

2.10.3. TRENDS - Trend of time series

Synopsis

\[
\text{trend[,equal]} \text{ infile outfile1 outfile2}
\]

Description

The values of the input file infile are assumed to be distributed as \(N(a + bt, \sigma^2)\) with unknown \(a, b\) and \(\sigma^2\). This operator estimates the parameter \(a\) and \(b\). For every field element \(x\) only those timesteps \(t\) belong to the sample \(S(x)\), which have \(i(t, x) \neq \text{miss}\). It is

\[
\alpha_1(1, x) = -\frac{1}{\# S(x)} \sum_{t \in S(x)} i(t, x) - b(x) \left( -\frac{1}{\# S(x)} \sum_{t \in S(x)} t \right)
\]

and

\[
\alpha_2(1, x) = \sum_{t \in S(x)} \left( i(t, x) - \frac{1}{\# S(x)} \sum_{t' \in S(x)} i(t', x) \right) \left( t - \frac{1}{\# S(x)} \sum_{t' \in S(x)} t' \right)
\]

Thus the estimation for \(a\) is stored in outfile1 and that for \(b\) is stored in outfile2. To subtract the trend from the data see operator subtrend. It is assumed that all timesteps are equidistant, if this is not the case set the parameter equal=false.

Parameter

\[
equal \quad \text{BOOL} \quad \text{Set to false for unequal distributed timesteps (default: true)}
\]
2.10.4. TRENDARITH - Add or subtract a trend

Synopsis

\(<operator>[,equal] \) infile1 infile2 infile3 outfile

Description

This module is for adding or subtracting a trend computed by the operator trend.

Operators

addtrend Add trend
It is
\[ o(t, x) = i_1(t, x) + (i_2(1, x) + i_3(1, x) \cdot t) \]
where \( t \) is the timesteps.

subtrend Subtract trend
It is
\[ o(t, x) = i_1(t, x) - (i_2(1, x) + i_3(1, x) \cdot t) \]
where \( t \) is the timesteps.

Parameter

equal BOOL Set to false for unequal distributed timesteps (default: true)

Example

The typical call for detrending the data in infile and storing the detrended data in outfile is:

```bash
  cdo trend infile afile bfile
  cdo subtrend infile afile bfile outfile
```

The result is identical to a call of the operator detrend:

```bash
  cdo detrend infile outfile
```
2.11. EOFs

This section contains modules to compute Empirical Orthogonal Functions and - once they are computed - their principal coefficients.

An introduction to the theory of principal component analysis as applied here can be found in:

Principal Component Analysis in Meteorology and Oceanography [Preisendorfer]

Details about calculation in the time- and spatial spaces are found in:

Statistical Analysis in Climate Research [vonStorch]

EOFs are defined as the eigen values of the scatter matrix (covariance matrix) of the data. For the sake of simplicity, samples are regarded as time series of anomalies \((z(t)), t \in \{1, \ldots, n\}\) of (column-) vectors \(z(t)\) with \(p\) entries (where \(p\) is the gridsize). Thus, using the fact, that \(z_j(t)\) are anomalies, i.e.

\[
\langle z_j \rangle = n^{-1} \sum_{i=1}^{n} z_j(i) = 0 \quad \forall \ 1 \leq j \leq p
\]

the scatter matrix \(S\) can be written as

\[
S = \sum_{t=1}^{n} \left[ \sqrt{W z(t)} \right] \left[ \sqrt{W z(t)} \right]^T
\]

where \(W\) is the diagonal matrix containing the area weight of cell \(p_0\) in \(z\) at \(W(x, x)\).

The matrix \(S\) has a set of orthonormal eigenvectors \(e_j, j = 1, \ldots, p\), which are called empirical orthogonal functions (EOFs) of the sample \(z\). (Please note, that \(e_j\) is the eigenvector of \(S\) and not the weighted eigen-vector which would be \(W e_j\).) Let the corresponding eigenvalues be denoted \(\lambda_j\). The vectors \(e_j\) are spatial patterns which explain a certain amount of variance of the time series \(z(t)\) that is related linearly to \(\lambda_j\). Thus, the spatial pattern defined by the first eigenvector (the one with the largest eigenvalue \(\lambda_1\)) is the pattern which explains a maximum possible amount of variance of the sample \(z(t)\). The orthonormality of eigenvectors reads as

\[
\sum_{x=1}^{p} \left[ \sqrt{W(x, x)} e_j(x) \right] \left[ \sqrt{W(x, x)} e_k(x) \right] = \sum_{x=1}^{p} W(x, x) e_j(x) e_k(x) = \begin{cases} 0 & \text{if } j \neq k \\ 1 & \text{if } j = k \end{cases}
\]

If all EOFs \(e_j\) with \(\lambda_j \neq 0\) are calculated, the data can be reconstructed from

\[
z(t, x) = \sum_{j=1}^{p} W(x, x) a_j(t) e_j(x)
\]

where \(a_j\) are called the principal components or principal coefficients or EOF coefficients of \(z\). These coefficients - as readily seen from above - are calculated as the projection of an EOF \(e_j\) onto a time step of the data sample \(z(t_0)\) as

\[
a_j(t_0) = \sum_{x=1}^{p} \left[ \sqrt{W(x, x)} e_j(x) \right] \left[ \sqrt{W(x, x)} z(t_0, x) \right] = \left[ \sqrt{W z(t_0)} \right]^T \left[ \sqrt{W e_j} \right].
\]

Here is a short overview of all operators in this section:

- `eof` Calculate EOFs in spatial or time space
- `eoftime` Calculate EOFs in time space
- `eofspatial` Calculate EOFs in spatial space
- `eof3d` Calculate 3-Dimensional EOFs in time space
- `eofcoeff` Calculate principal coefficients of EOFs
2.11.1. EOFs - Empirical Orthogonal Functions

Synopsis

\[ <\text{operator}>, \text{neof} \ \text{infile} \ \text{outfile1} \ \text{outfile2} \]

Description

This module calculates empirical orthogonal functions of the data in infile as the eigen values of the scatter matrix (covariance matrix) \( S \) of the data sample \( z(t) \). A more detailed description can be found above.

Please note, that the input data are assumed to be anomalies.

If operator eof is chosen, the EOFs are computed in either time or spatial space, whichever is the fastest. If the user already knows, which computation is faster, the module can be forced to perform a computation in time- or gridspace by using the operators eoftime or eofspatial, respectively. This can enhance performance, especially for very long time series, where the number of timesteps is larger than the number of grid-points. Data in infile are assumed to be anomalies. If they are not, the behavior of this module is not well defined. After execution outfile1 will contain all eigen-values and outfile2 the eigenvectors \( e_j \). All EOFs and eigen-values are computed. However, only the first \( \text{neof} \) EOFs are written to outfile2. Nonetheless, outfile1 contains all eigen-values.

Missing values are not fully supported. Support is only checked for non-changing masks of missing values in time. Although there still will be results, they are not trustworthy, and a warning will occur. In the latter case we suggest to replace missing values by 0 in infile.

Operators

- \text{eof} \quad \text{Calculate EOFs in spatial or time space}
- \text{eoftime} \quad \text{Calculate EOFs in time space}
- \text{eofspatial} \quad \text{Calculate EOFs in spatial space}
- \text{eof3d} \quad \text{Calculate 3-Dimensional EOFs in time space}

Parameter

\begin{center}
\begin{tabular}{ll}
\text{neof} & \text{INTEGER} \quad \text{Number of eigen functions} \\
\end{tabular}
\end{center}

Environment

- \text{CDO_SVD_MODE} \quad \text{Is used to choose the algorithm for eigenvalue calculation. Options are 'jacobi' for a one-sided parallel jacobi-algorithm (only executed in parallel if -P flag is set) and 'danielson_lanczos' for a non-parallel d/l algorithm. The default setting is 'jacobi'.}
- \text{CDO_WEIGHT_MODE} \quad \text{It is used to set the weight mode. The default is 'off'. Set it to 'on' for a weighted version.}
- \text{MAX_JACOBI_ITER} \quad \text{Is the maximum integer number of annihilation sweeps that is executed if the jacobi-algorithm is used to compute the eigen values. The default value is 12.}
- \text{FNORM_PRECISION} \quad \text{Is the Frobenius norm of the matrix consisting of an annihilation pair of eigenvectors that is used to determine if the eigenvectors have reached a sufficient level of convergence. If all annihilation-pairs of vectors have a norm below this value, the computation is considered to have converged properly. Otherwise, a warning will occur. The default value 1e-12.}
**Example**

To calculate the first 40 EOFs of a data-set containing anomalies use:

```bash
cdo eof,40 infile outfile1 outfile2
```

If the dataset does not contain anomalies, process them first, and use:

```bash
cdo sub infile1 -timmean infile1 anom_file
cdo eof,40 anom_file outfile1 outfile2
```
2.11.2. EOFCOEFF - Principal coefficients of EOFs

**Synopsis**

```
eofcoeff infile1 infile2 obase
```

**Description**

This module calculates the time series of the principal coefficients for given EOF (empirical orthogonal functions) and data. Time steps in `infile1` are assumed to be the EOFs, time steps in `infile2` are assumed to be the time series. Note, that this operator calculates a non weighted dot product of the fields in `infile1` and `infile2`. For consistency set the environment variable `CDO_WEIGHT_MODE=off` when using `eof` or `eof3d`. Given a set of EOFs $e_j$ and a time series of data $z(t)$ with $p$ entries for each timestep from which $e_j$ have been calculated, this operator calculates the time series of the projections of data onto each EOF

$$o_j(t) = \sum_{x=1}^{p} z(t,x)e_j(x)$$

There will be a separate file $o_j$ for the principal coefficients of each EOF.

As the EOFs $e_j$ are uncorrelated, so are their principal coefficients, i.e.

$$\sum_{t=1}^{n} o_j(t)o_k(t) = \begin{cases} 0 & \text{if } j \neq k \\ \lambda_j & \text{if } j = k \end{cases} \text{ with } \sum_{t=1}^{n} o_j(t) = 0 \forall j \in \{1,\ldots, p\}.$$  

There will be a separate file containing a time series of principal coefficients with time information from `infile2` for each EOF in `infile1`. Output files will be numbered as `<obase><neof><suffix>` where `neof+1` is the number of the EOF (timestep) in `infile1` and `suffix` is the filename extension derived from the file format.

**Environment**

`CDO_FILE_SUFFIX` Set the default file suffix. This suffix will be added to the output file names instead of the filename extension derived from the file format. Set this variable to NULL to disable the adding of a file suffix.

**Example**

To calculate principal coefficients of the first 40 EOFs of `anom_file`, and write them to files beginning with `obase`, use:

```
export CDO_WEIGHT_MODE=off
cdo eof,40 anom_file eval_file eof_file
cdo eofcoeff eof_file anom_file obase
```

The principal coefficients of the first EOF will be in the file `obase000000.nc` (and so forth for higher EOFs, $n$th EOF will be in `obase<n-1>`).

If the dataset `infile` does not contain anomalies, process them first, and use:

```
export CDO_WEIGHT_MODE=off
cdo sub infile -timmean infile anom_file
cdo eof,40 anom_file eval_file eof_file
cdo eofcoeff eof_file anom_file obase
```
2.12. Interpolation

This section contains modules to interpolate datasets. There are several operators to interpolate horizontal fields to a new grid. Some of those operators can handle only 2D fields on a regular rectangular grid. Vertical interpolation of 3D variables is possible from hybrid model levels to height or pressure levels. Interpolation in time is possible between time steps and years.

Here is a short overview of all operators in this section:

- **remapbil**  
  Bilinear interpolation

- **genbil**  
  Generate bilinear interpolation weights

- **remapbic**  
  Bicubic interpolation

- **genbic**  
  Generate bicubic interpolation weights

- **remapnn**  
  Nearest neighbor remapping

- **gennn**  
  Generate nearest neighbor remap weights

- **remapdis**  
  Distance weighted average remapping

- **gendis**  
  Generate distance weighted average remap weights

- **remapcon**  
  First order conservative remapping

- **gencon**  
  Generate 1st order conservative remap weights

- **remapcon2**  
  Second order conservative remapping

- **gencon2**  
  Generate 2nd order conservative remap weights

- **remaplaf**  
  Largest area fraction remapping

- **genlaf**  
  Generate largest area fraction remap weights

- **remap**  
  Grid remapping

- **remapeta**  
  Remap vertical hybrid level

- **ml2pl**  
  Model to pressure level interpolation

- **ml2hl**  
  Model to height level interpolation

- **ap2pl**  
  Air pressure to pressure level interpolation

- **gh2hl**  
  Geometric height to height level interpolation

- **intlevel**  
  Linear level interpolation

- **intlevel3d**  
  Linear level interpolation onto a 3D vertical coordinate

- **intlevelx3d**  
  Like intlevel3d but with extrapolation

- **intttime**  
  Interpolation between timesteps

- **intntime**  
  Interpolation between timesteps

- **intyear**  
  Interpolation between two years
2.12.1. REMAPBIL - Bilinear interpolation

Synopsis

\(<\text{operator}>\),grid infile outfile

Description

This module contains operators for a bilinear remapping of fields between grids in spherical coordinates. The interpolation is based on an adapted SCRIP library version. For a detailed description of the interpolation method see [SCRIP]. This interpolation method only works on quadrilateral curvilinear source grids. Below is a schematic illustration of the bilinear remapping:

The figure on the left side shows the input data on a regular lon/lat source grid and on the right side the remapped result on an unstructured triangular target grid. The figure in the middle shows the input data with the target grid. Grid cells with missing value are grey colored.

Operators

- **remapbil**  
  Bilinear interpolation  
  Performs a bilinear interpolation on all input fields.

- **genbil**  
  Generate bilinear interpolation weights  
  Generates bilinear interpolation weights for the first input field and writes the result to a file. The format of this file is NetCDF following the SCRIP convention. Use the operator `remap` to apply this remapping weights to a data file with the same source grid.

Parameter

- **grid**  
  STRING  
  Target grid description file or name

Environment

- **REMAP_EXTRAPOLATE**  
  This variable is used to switch the extrapolation feature ‘on’ or ‘off’. By default the extrapolation is enabled for circular grids.

Example

Say `infile` contains fields on a quadrilateral curvilinear grid. To remap all fields bilinear to a Gaussian N32 grid, type:

```
cdo remapbil,n32 infile outfile
```
2.12.2. REMAPBIC - Bicubic interpolation

Synopsis

\(<\text{operator}>\),\text{grid}\ \text{infile} \ \text{outfile}

Description

This module contains operators for a bicubic remapping of fields between grids in spherical coordinates. The interpolation is based on an adapted SCRIP library version. For a detailed description of the interpolation method see [SCRIP]. This interpolation method only works on quadrilateral curvilinear source grids. Below is a schematic illustration of the bicubic remapping:

![Schematic illustration of bicubic remapping](image)

The figure on the left side shows the input data on a regular lon/lat source grid and on the right side the remapped result on an unstructured triangular target grid. The figure in the middle shows the input data with the target grid. Grid cells with missing value are grey colored.

Operators

- **remapbic**  
  Bicubic interpolation  
  Performs a bicubic interpolation on all input fields.

- **genbic**  
  Generate bicubic interpolation weights  
  Generates bicubic interpolation weights for the first input field and writes the result to a file. The format of this file is NetCDF following the SCRIP convention. Use the operator remap to apply this remapping weights to a data file with the same source grid.

Parameter

- **grid**  
  STRING  
  Target grid description file or name

Environment

- **REMAP_EXTRAPOLATE**  
  This variable is used to switch the extrapolation feature 'on' or 'off'. By default the extrapolation is enabled for circular grids.

Example

Say \text{infile} contains fields on a quadrilateral curvilinear grid. To remap all fields bicubic to a Gaussian N32 grid, type:

\[
\text{cdo remapbic,n32 infile outfile}
\]
2.12.3. REMAPNN - Nearest neighbor remapping

Synopsis

\(<\text{operator}>\),grid infile outfile

Description

This module contains operators for a nearest neighbor remapping of fields between grids in spherical coordinates. Below is a schematic illustration of the nearest neighbor remapping:

The figure on the left side shows the input data on a regular lon/lat source grid and on the right side the remapped result on an unstructured triangular target grid. The figure in the middle shows the input data with the target grid. Grid cells with missing value are grey colored.

Operators

- **remapnn** Nearest neighbor remapping
  Performs a nearest neighbor remapping on all input fields.

- **gennn** Generate nearest neighbor remap weights
  Generates nearest neighbor remapping weights for the first input field and writes the result to a file. The format of this file is NetCDF following the SCRIP convention. Use the operator **remap** to apply this remapping weights to a data file with the same source grid.

Parameter

- **grid** STRING Target grid description file or name

Environment

- **REMAP_EXTRAPOLATE** This variable is used to switch the extrapolation feature 'on' or 'off'. By default the extrapolation is enabled for this remapping method.
  
- **CDO_GRIDSEARCH_RADIUS** Grid search radius in degree, default 180 degree.
2.12.4. REMAPDIS - Distance weighted average remapping

Synopsis

remapdis, grid[,neighbors] infile outfile

gendis, grid infile outfile

Description

This module contains operators for an inverse distance weighted average remapping of the four nearest neighbor values of fields between grids in spherical coordinates. The interpolation is based on an adapted SCRIP library version. For a detailed description of the interpolation method see [SCRIP]. Below is a schematic illustration of the distance weighted average remapping:

The figure on the left side shows the input data on a regular lon/lat source grid and on the right side the remapped result on an unstructured triangular target grid. The figure in the middle shows the input data with the target grid. Grid cells with missing value are grey colored.

Operators

remapdis  Distance weighted average remapping
Performs an inverse distance weighted average remapping of the nearest neighbors value on all input fields. The default number of nearest neighbors is 4.

gendis  Generate distance weighted average remap weights
Generates distance weighted average remapping weights of the four nearest neighbor values for the first input field and writes the result to a file. The format of this file is NetCDF following the SCRIP convention. Use the operator remap to apply this remapping weights to a data file with the same source grid.

Parameter

grid  STRING  Target grid description file or name

neighbors  INTEGER  Number of nearest neighbors

Environment

REMAP_EXTRAPOLATE  This variable is used to switch the extrapolation feature 'on' or 'off'. By default the extrapolation is enabled for this remapping method.

CDO_GRIDSEARCH_RADIUS  Grid search radius in degree, default 180 degree.
2.12.5. REMAPCON - First order conservative remapping

Synopsis

<operator>.grid infile outfile

Description

This module contains operators for a first order conservative remapping of fields between grids in spherical coordinates. The operators in this module uses code from the YAC software package to compute the conservative remapping weights. For a detailed description of the interpolation method see [YAC]. The interpolation method is completely general and can be used for any grid on a sphere. The search algorithm for the conservative remapping requires that no grid cell occurs more than once. Below is a schematic illustration of the 1st order conservative remapping:

The figure on the left side shows the input data on a regular lon/lat source grid and on the right side the remapped result on an unstructured triangular target grid. The figure in the middle shows the input data with the target grid. Grid cells with missing value are grey colored.

Operators

remapcon  First order conservative remapping
Performs a first order conservative remapping on all input fields.

gencon  Generate 1st order conservative remap weights
Generates first order conservative remapping weights for the first input field and writes the result to a file. The format of this file is NetCDF following the SCRIP convention. Use the operator remap to apply this remapping weights to a data file with the same source grid.

Parameter

grid  STRING  Target grid description file or name

Environment

CDO_REMAP_NORM  This variable is used to choose the normalization of the conservative interpolation. By default CDO_REMAP_NORM is set to 'fracarea'. 'fracarea' uses the sum of the non-masked source cell intersected areas to normalize each target cell field value. This results in a reasonable flux value but the flux is not locally conserved. The option 'destarea' uses the total target cell area to normalize each target cell field value. Local flux conservation is ensured, but unreasonable flux values may result.
REMAP_AREA_MIN   This variable is used to set the minimum destination area fraction. The default of this variable is 0.0.

Example

Say infile contains fields on a quadrilateral curvilinear grid. To remap all fields conservative to a Gaussian N32 grid, type:

```
cdo remapcon,n32 infile outfile
```
2.12.6. REMAPCON2 - Second order conservative remapping

**Synopsis**

\[\text{<operator>}, \text{grid} \text{ infile outfile}\]

**Description**

This module contains operators for a second order conservative remapping of fields between grids in spherical coordinates. The interpolation is based on an adapted SCRIP library version. For a detailed description of the interpolation method see [SCRIP]. The interpolation method is completely general and can be used for any grid on a sphere. The search algorithm for the conservative remapping requires that no grid cell occurs more than once. Below is a schematic illustration of the 2nd order conservative remapping:

The figure on the left side shows the input data on a regular lon/lat source grid and on the right side the remapped result on an unstructured triangular target grid. The figure in the middle shows the input data with the target grid. Grid cells with missing value are grey colored.

**Operators**

- **remapcon2**  
  Second order conservative remapping  
  Performs a second order conservative remapping on all input fields.

- **gencon2**  
  Generate 2nd order conservative remap weights  
  Generates second order conservative remapping weights for the first input field and writes the result to a file. The format of this file is NetCDF following the SCRIP convention. Use the operator `remap` to apply this remapping weights to a data file with the same source grid.

**Parameter**

- **grid**  
  STRING  
  Target grid description file or name

**Environment**

- **CDO_REMAP_NORM**  
  This variable is used to choose the normalization of the conservative interpolation. By default CDO_REMAP_NORM is set to 'fracarea'. 'fracarea' uses the sum of the non-masked source cell intersected areas to normalize each target cell field value. This results in a reasonable flux value but the flux is not locally conserved. The option 'destarea' uses the total target cell area to normalize each target cell field value. Local flux conservation is ensured, but unreasonable flux values may result.
REMAP\_AREA\_MIN  This variable is used to set the minimum destination area fraction. The default of this variable is 0.0.

**Note**

The SCRIP conservative remapping method doesn’t work correctly for some grid combinations.

**Example**

Say *infile* contains fields on a quadrilateral curvilinear grid. To remap all fields conservative (2nd order) to a Gaussian N32 grid, type:

```
cdo remapcon2,n32 infile outfile
```
2.12.7. REMAPLAF - Largest area fraction remapping

Synopsis

<operator>,grid infile outfile

Description

This module contains operators for a largest area fraction remapping of fields between grids in spherical coordinates. The operators in this module use code from the YAC software package to compute the largest area fraction. For a detailed description of the interpolation method see [YAC]. The interpolation method is completely general and can be used for any grid on a sphere. The search algorithm for this remapping method requires that no grid cell occurs more than once. Below is a schematic illustration of the largest area fraction conservative remapping:

The figure on the left side shows the input data on a regular lon/lat source grid and on the right side the remapped result on an unstructured triangular target grid. The figure in the middle shows the input data with the target grid. Grid cells with missing value are grey colored.

Operators

- remaplaf: Largest area fraction remapping
  Performs a largest area fraction remapping on all input fields.
- genlaf: Generate largest area fraction remap weights
  Generates largest area fraction remapping weights for the first input field and writes the result to a file. The format of this file is NetCDF following the SCRIP convention. Use the operator remap to apply this remapping weights to a data file with the same source grid.

Parameter

- grid STRING Target grid description file or name

Environment

- REMAP_AREA_MIN This variable is used to set the minimum destination area fraction. The default of this variable is 0.0.
2.12.8. REMAP - Grid remapping

Synopsis

\texttt{remap},grid,weights \texttt{infile outfile}

Description

Interpolation between different horizontal grids can be a very time-consuming process. Especially if the data are on an unstructured and/or a large grid. In this case the interpolation process can be split into two parts. Firstly the generation of the interpolation weights, which is the most time-consuming part. These interpolation weights can be reused for every remapping process with the operator \texttt{remap}. This operator remaps all input fields to a new horizontal grid. The remap type and the interpolation weights of one input grid are read from a NetCDF file. More weights are computed if the input fields are on different grids. The NetCDF file with the weights should follow the [SCRIP] convention. Normally these weights come from a previous call to one of the genXXX operators (e.g. \texttt{genbil}) or were created by the original SCRIP package.

Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grid</td>
<td>STRING</td>
<td>Target grid description file or name</td>
</tr>
<tr>
<td>weights</td>
<td>STRING</td>
<td>Interpolation weights (SCRIP NetCDF file)</td>
</tr>
</tbody>
</table>

Environment

- \texttt{CDO_REMAP_NORM} This variable is used to choose the normalization of the conservative interpolation. By default \texttt{CDO_REMAP_NORM} is set to 'fracarea'. 'fracarea' uses the sum of the non-masked source cell intersected areas to normalize each target cell field value. This results in a reasonable flux value but the flux is not locally conserved. The option 'destarea' uses the total target cell area to normalize each target cell field value. Local flux conservation is ensured, but unreasonable flux values may result.
- \texttt{REMAP_EXTRAPOLATE} This variable is used to switch the extrapolation feature 'on' or 'off'. By default the extrapolation is enabled for remapdis, remapnn and for circular grids.
- \texttt{REMAP_AREA_MIN} This variable is used to set the minimum destination area fraction. The default of this variable is 0.0.
- \texttt{CDO_GRIDSEARCH_RADIUS} Grid search radius in degree, default 180 degree.

Example

Say \texttt{infile} contains fields on a quadrilateral curvilinear grid. To remap all fields bilinear to a Gaussian N32 grid use:

```
cdo genbil,n32 infile remapweights.nc
```
```
cdo remap,n32,remapweights.nc infile outfile
```

The result will be the same as:

```
cdo remapbil,n32 infile outfile
```
2.12.9. REMAPETA - Remap vertical hybrid level

Synopsis

```plaintext
remapeta.vct[,oro] infile outfile
```

Description

This operator interpolates between different vertical hybrid levels. This include the preparation of consistent data for the free atmosphere. The procedure for the vertical interpolation is based on the HIRLAM scheme and was adapted from [INTERA]. The vertical interpolation is based on the vertical integration of the hydrostatic equation with few adjustments. The basic tasks are the following one:

- at first integration of hydrostatic equation
- extrapolation of surface pressure
- Planetary Boundary-Layer (PBL) proutfile interpolation
- interpolation in free atmosphere
- merging of both proutfiles
- final surface pressure correction

The vertical interpolation corrects the surface pressure. This is simply a cut-off or an addition of air mass. This mass correction should not influence the geostrophic velocity field in the middle troposphere. Therefore the total mass above a given reference level is conserved. As reference level the geopotential height of the 400 hPa level is used. Near the surface the correction can affect the vertical structure of the PBL. Therefore the interpolation is done using the potential temperature. But in the free atmosphere above a certain n (n=0.8 defining the top of the PBL) the interpolation is done linearly. After the interpolation both proutfiles are merged. With the resulting temperature/pressure correction the hydrostatic equation is integrated again and adjusted to the reference level finding the final surface pressure correction. A more detailed description of the interpolation can be found in [INTERA]. This operator requires all variables on the same horizontal grid.

Parameter

- **vct**: STRING
  File name of an ASCII dataset with the vertical coordinate table
- **oro**: STRING
  File name with the orography (surf. geopotential) of the target dataset (optional)

Environment

- **REMAPETA_PTOP**: Sets the minimum pressure level for condensation. Above this level the humidity is set to the constant 1.E-6. The default value is 0 Pa.

Note

The code numbers or the variable names of the required parameter have to follow the [ECHAM] convention.

Use the sinfo command to test if your vertical coordinate system is recognized as hybrid system.

In case remapeta complains about not finding any data on hybrid model levels you may wish to use the setzaxis command to generate a zaxis description which conforms to the ECHAM convention. See section "1.4 Z-axis description" for an example how to define a hybrid Z-axis.
Example

To remap between different hybrid model level data use:

cdo remapeta,vct infile outfile

Here is an example vct file with 19 hybrid model level:

2.12.10. VERTINTML - Vertical interpolation

Synopsis

\[ \text{ml2pl,plevels} \] infile outfile
\[ \text{ml2hl,hlevels} \] infile outfile

Description

Interpolates 3D variables on hybrid sigma pressure level to pressure or height levels. The input file should contain the log. surface pressure or the surface pressure. To extrapolate the temperature, the surface geopotential is also needed. It is assumed that the geopotential heights are located on the hybrid layer interfaces. For the lowest layer of geopotential heights the surface geopotential is required. The pressure, temperature, geopotential height, and surface geopotential are identified by their GRIB1 code number or NetCDF CF standard name. Supported parameter tables are: WMO standard table number 2 and ECMWF local table number 128.

<table>
<thead>
<tr>
<th>CF standard name</th>
<th>Units</th>
<th>GRIB 1 code</th>
</tr>
</thead>
<tbody>
<tr>
<td>surface_air_pressure</td>
<td>Pa</td>
<td>134</td>

<td>156</td>
</tr>
</tbody>
</table>

Use the alias \text{ml2plx/ml2hlx} or the environment variable EXTRAPOLATE to extrapolate missing values. This operator requires all variables on the same horizontal grid. Missing values in the input data are not supported.

Operators

\text{ml2pl} \quad \text{Model to pressure level interpolation}
Interpolates 3D variables on hybrid sigma pressure level to pressure level.

\text{ml2hl} \quad \text{Model to height level interpolation}
Interpolates 3D variables on hybrid sigma pressure level to height level. The procedure is the same as for the operator \text{ml2pl} except for the pressure levels being calculated from the heights by: \( plevel = 101325 \times exp(hlevel/ - 7000) \)

Parameter

\text{plevels} FLOAT \quad \text{Pressure levels in pascal}

\text{hlevels} FLOAT \quad \text{Height levels in meter}

Environment

EXTRAPOLATE \quad \text{If set to 1 extrapolate missing values.}

Example

To interpolate hybrid model level data to pressure levels of 925, 850, 500 and 200 hPa use:

\[ \text{cdo ml2pl,92500,85000,50000,20000} \] infile outfile
2.12.11. VERTINTAP - Vertical pressure interpolation

Synopsis

```
ap2pl,plevels infile outfile
```

Description

Interpolate 3D variables on hybrid sigma height coordinates to pressure levels. The input file must contain the 3D air pressure in pascal. The air pressure is identified by the NetCDF CF standard name `air_pressure`. Use the alias `ap2plx` or the environment variable `EXTRAPOLATE` to extrapolate missing values. This operator requires all variables on the same horizontal grid.

Parameter

- `plevels` FLOAT Comma-separated list of pressure levels in pascal

Environment

- `EXTRAPOLATE` If set to 1 extrapolate missing values.

Note

This is a specific implementation for NetCDF files from the ICON model, it may not work with data from other sources.

Example

To interpolate 3D variables on hybrid sigma height level to pressure levels of 925, 850, 500 and 200 hPa use:

```
cdo ap2pl,92500,85000,50000,20000 infile outfile
```
2.12.12. VERTINTGH - Vertical height interpolation

Synopsis

`gh2hl.hlevels infile outfile`

Description

Interpolate 3D variables on hybrid sigma height coordinates to height levels. The input file must contain the 3D geometric height in meter. The geometric height is identified by the NetCDF CF standard name `geometric_height_at_full_level_center`. Use the alias `gh2hlx` or the environment variable `EXTRAPOLATE` to extrapolate missing values. This operator requires all variables on the same horizontal grid.

Parameter

- `hlevels` FLOAT Comma-separated list of height levels in meter

Environment

- `EXTRAPOLATE` If set to 1 extrapolate missing values.

Note

This is a specific implementation for NetCDF files from the ICON model, it may not work with data from other sources.

Example

To interpolate 3D variables on hybrid sigma height level to height levels of 20, 100, 500, 1000, 5000, 10000 and 20000 meter use:

```
cdo gh2hl,20,100,500,1000,5000,10000,20000 infile outfile
```
2.12.13. INTLEVEL - Linear level interpolation

Synopsis

```
intlevel,levels infile outfile
```

Description

This operator performs a linear vertical interpolation of 3D variables.

Parameter

```
levels FLOAT Comma-separated list of target levels
```

Example

To interpolate 3D variables on height levels to a new set of height levels use:

```
cdo intlevel,10,50,100,500,1000 infile outfile
```

2.12.14. INTLEVEL3D - Linear level interpolation from/to 3D vertical coordinates

Synopsis

```
<operator>,tgtcoordinate infile1 infile2 outfile
```

Description

This operator performs a linear vertical interpolation of 3D variables fields with given 3D vertical coordinates. `infile1` contains the 3D data variables and `infile2` the 3D vertical source coordinate. The parameter `tgtcoordinate` is a datafile with the 3D vertical target coordinate.

Operators

```
intlevel3d Linear level interpolation onto a 3D vertical coordinate
intlevelx3d like intlevel3d but with extrapolation
```

Parameter

```
tgtcoordinate STRING filename for 3D vertical target coordinates
```

Example

To interpolate 3D variables from one set of 3D height levels into another one where

- `infile2` contains a single 3D variable, which represents the source 3D vertical coordinate
- `infile1` contains the source data, which the vertical coordinate from `infile2` belongs to
- `tgtcoordinate` only contains the target 3D height levels

```
cdo intlevel3d,tgtcoordinate infile1 infile2 outfile
```
2.12.15. INTTIME - Time interpolation

Synopsis

inttime, date, time[, inc] infile outfile
intntime, n infile outfile

Description

This module performs linear interpolation between timesteps. Interpolation is only performed if both values exist. If both values are missing values, the result is also a missing value. If only one value exists, it is taken if the time weighting is greater than or equal to 0.5. So no new value will be created at existing time steps, if the value is missing there.

Operators

inttime        Interpolation between timesteps
This operator creates a new dataset by linear interpolation between timesteps. The user has to define the start date/time with an optional increment.

intntime       Interpolation between timesteps
This operator performs linear interpolation between timesteps. The user has to define the number of timesteps from one timestep to the next.

Parameter

- **date**      STRING    Start date (format YYYY-MM-DD)
- **time**      STRING    Start time (format hh:mm:ss)
- **inc**       STRING    Optional increment (seconds, minutes, hours, days, months, years) [default: 0hour]
- **n**         INTEGER   Number of timesteps from one timestep to the next

Example

Assumed a 6 hourly dataset starts at 1987-01-01 12:00:00. To interpolate this time series to a one hourly dataset use:

    cdo inttime,1987-01-01,12:00:00,1hour infile outfile
2.12.16. INTYEAR - Year interpolation

Synopsis

```plaintext
intyear years infile1 infile2 obase
```

Description

This operator performs linear interpolation between two years, timestep by timestep. The input files need to have the same structure with the same variables. The output files will be named `<obase><yyyy><suffix>` where `yyyy` will be the year and `suffix` is the filename extension derived from the file format.

Parameter

```plaintext
years INTEGER Comma-separated list or first/last[/inc] range of years
```

Environment

```plaintext
CDO_FILE_SUFFIX Set the default file suffix. This suffix will be added to the output file names instead of the filename extension derived from the file format. Set this variable to NULL to disable the adding of a file suffix.
```

Note

This operator needs to open all output files simultaneously. The maximum number of open files depends on the operating system!

Example

Assume there are two monthly mean datasets over a year. The first dataset has 12 timesteps for the year 1985 and the second one for the year 1990. To interpolate the years between 1985 and 1990 month by month use:

```plaintext
```

Example result of `dir year*` for NetCDF datasets:

```plaintext
```
2.13. Transformation

This section contains modules to perform spectral transformations.

Here is a short overview of all operators in this section:

- **sp2gp**: Spectral to gridpoint
- **gp2sp**: Gridpoint to spectral
- **sp2sp**: Spectral to spectral
- **dv2ps**: D and V to velocity potential and stream function
- **dv2uv**: Divergence and vorticity to U and V wind
- **uv2dv**: U and V wind to divergence and vorticity
- **fourier**: Fourier transformation
2.13.1. SPECTRAL - Spectral transformation

Synopsis

\(<operator>[,gridtype]\) infile outfile

Description

This module transforms fields on a global regular Gaussian grid to spectral coefficients and vice versa. The transformation is achieved by applying Fast Fourier Transformation (FFT) first and direct Legendre Transformation afterwards in gp2sp. In sp2gp the inverse Legendre Transformation and inverse FFT are used. Missing values are not supported.

The relationship between the spectral resolution, governed by the truncation number T, and the grid resolution depends on the number of grid points at which the shortest wavelength field is represented. For a grid with 2N points between the poles (so 4N grid points in total around the globe) the relationship is:

- **linear grid**: the shortest wavelength is represented by 2 grid points \( \rightarrow 4N \approx 2(TL + 1) \)
- **quadratic grid**: the shortest wavelength is represented by 3 grid points \( \rightarrow 4N \approx 3(TQ + 1) \)
- **cubic grid**: the shortest wavelength is represented by 4 grid points \( \rightarrow 4N \approx 4(TC + 1) \)

The quadratic grid is used by ECHAM and ERA15. ERA40 is using a linear Gaussian grid reflected by the TL notation.

The following table shows the calculation of the number of latitudes and the triangular truncation for the different grid types:

<table>
<thead>
<tr>
<th>Gridtype</th>
<th>Number of latitudes: nlat</th>
<th>Triangular truncation: ntr</th>
</tr>
</thead>
<tbody>
<tr>
<td>linear</td>
<td>( NINT((ntr*2 + 1)/2) )</td>
<td>( (nlat^2 - 1) / 2 )</td>
</tr>
<tr>
<td>quadratic</td>
<td>( NINT((ntr*3 + 1)/2) )</td>
<td>( (nlat^2 - 1) / 3 )</td>
</tr>
<tr>
<td>cubic</td>
<td>( NINT((ntr*4 + 1)/2) )</td>
<td>( (nlat^2 - 1) / 4 )</td>
</tr>
</tbody>
</table>

Operators

- **sp2gp** Spectral to gridpoint
  Convert all spectral fields to a global regular Gaussian grid.
- **gp2sp** Gridpoint to spectral
  Convert all Gaussian gridpoint fields to spectral fields.

Parameter

- **gridtype** STRING Type of the grid: quadratic, linear, cubic (default: quadratic)

Note

To speed up the calculations, the Legendre polynomials are kept in memory. This requires a relatively large amount of memory. This is for example 12GB for T1279 data.

Example

To transform spectral coefficients from T106 to N80 Gaussian grid use:

```
cdo sp2gp infile outfile
```

To transform spectral coefficients from TL159 to N80 Gaussian grid use:

```
cdo sp2gp,linear infile outfile
```
2.13.2. SPECCONV - Spectral conversion

Synopsis

\texttt{sp2sp, trunc infile outfile}

Description

Changed the triangular truncation of all spectral fields. This operator performs downward conversion by cutting the resolution. Upward conversions are achieved by filling in zeros.

Parameter

- \texttt{trunc} INTEGER New spectral resolution

2.13.3. WIND2 - D and V to velocity potential and stream function

Synopsis

\texttt{dv2ps infile outfile}

Description

Calculate spherical harmonic coefficients of velocity potential and stream function from spherical harmonic coefficients of relative divergence and vorticity. The divergence and vorticity need to have the names sd and svo or code numbers 155 and 138.
2.13.4. WIND - Wind transformation

Synopsis

\(<\text{operator}>[,\text{gridtype}]\ \text{in}file\ \text{out}file\)

Description

This module converts relative divergence and vorticity to U and V wind and vice versa. Divergence and vorticity are spherical harmonic coefficients in spectral space and U and V are on a global regular Gaussian grid. The Gaussian latitudes need to be ordered from north to south. Missing values are not supported.

The relationship between the spectral resolution, governed by the truncation number T, and the grid resolution depends on the number of grid points at which the shortest wavelength field is represented. For a grid with 2N points between the poles (so 4N grid points in total around the globe) the relationship is:

- **linear grid**: the shortest wavelength is represented by 2 grid points → 4N ≃ 2(TL + 1)
- **quadratic grid**: the shortest wavelength is represented by 3 grid points → 4N ≃ 3(TQ + 1)
- **cubic grid**: the shortest wavelength is represented by 4 grid points → 4N ≃ 4(TC + 1)

The quadratic grid is used by ECHAM and ERA15. ERA40 is using a linear Gaussian grid reflected by the TL notation.

The following table shows the calculation of the number of latitudes and the triangular truncation for the different grid types:

<table>
<thead>
<tr>
<th>Gridtype</th>
<th>Number of latitudes: nlat</th>
<th>Triangular truncation: ntr</th>
</tr>
</thead>
<tbody>
<tr>
<td>linear</td>
<td>(\text{NINT}(\text{ntr}*2 + 1)/2)</td>
<td>((\text{nlat}*2 - 1) / 2)</td>
</tr>
<tr>
<td>quadratic</td>
<td>(\text{NINT}(\text{ntr}*3 + 1)/2)</td>
<td>((\text{nlat}*2 - 1) / 3)</td>
</tr>
<tr>
<td>cubic</td>
<td>(\text{NINT}(\text{ntr}*4 + 1)/2)</td>
<td>((\text{nlat}*2 - 1) / 4)</td>
</tr>
</tbody>
</table>

Operators

- **dv2uv** Divergence and vorticity to U and V wind
  Calculate U and V wind on a Gaussian grid from spherical harmonic coefficients of relative divergence and vorticity. The divergence and vorticity need to have the names sd and svo or code numbers 155 and 138.

- **uv2dv** U and V wind to divergence and vorticity
  Calculate spherical harmonic coefficients of relative divergence and vorticity from U and V wind. The U and V wind need to be on a Gaussian grid and need to have the names u and v or the code numbers 131 and 132.

Parameter

- **gridtype** STRING Type of the grid: quadratic, linear (default: quadratic)

Note

To speed up the calculations, the Legendre polynoms are kept in memory. This requires a relatively large amount of memory. This is for example 12GB for T1279 data.
Example

Assume a dataset has at least spherical harmonic coefficients of divergence and vorticity. To transform the spectral divergence and vorticity to U and V wind on a Gaussian grid use:

```
cdo dv2uv infile outfile
```
2.13.5. FOURIER - Fourier transformation

Synopsis

\texttt{fourier,epsilon infile outfile}

Description

The fourier operator performs the fourier transformation or the inverse fourier transformation of all input fields. If the number of timesteps is a power of 2 then the algorithm of the Fast Fourier Transformation (FFT) is used.

It is

\[ a(t, x) = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} i(t, x) e^{i2\pi ij} \]

where a user given \texttt{epsilon} = -1 leads to the forward transformation and a user given \texttt{epsilon} = 1 leads to the backward transformation.

If the input stream \texttt{infile} consists only of complex fields, then the fields of \texttt{outfile}, computed by

\texttt{cdo -f ext fourier,1 -fourier,-1 infile outfile}

are the same than that of \texttt{infile}. For real input files see function \texttt{retocomplex}.

Parameter

\texttt{epsilon} \hspace{0.5cm} \texttt{INTEGER} \hspace{0.5cm} -1: forward transformation; 1: backward transformation

Note

Complex numbers can only be stored in NetCDF4 and EXTRA format.

This section contains modules to import and export data files which can not read or write directly with CDO.

Here is a short overview of all operators in this section:

- **import_binary**: Import binary data sets
- **import_cmsaf**: Import CM-SAF HDF5 files
- **import_amsr**: Import AMSR binary files
- **input**: ASCII input
- **inputsrv**: SERVICE ASCII input
- **inputext**: EXTRA ASCII input
- **output**: ASCII output
- **outputf**: Formatted output
- **outputint**: Integer output
- **outputsrv**: SERVICE ASCII output
- **outputext**: EXTRA ASCII output
- **outputtab**: Table output
- **gmtxyz**: GMT xyz format
- **gmtcells**: GMT multiple segment format
2.14.1. IMPORTBINARY - Import binary data sets

Synopsis

import_binary infile outfile

Description

This operator imports gridded binary data sets via a GrADS data descriptor file. The GrADS data descriptor file contains a complete description of the binary data as well as instructions on where to find the data and how to read it. The descriptor file is an ASCII file that can be created easily with a text editor. The general contents of a gridded data descriptor file are as follows:

- Filename for the binary data
- Missing or undefined data value
- Mapping between grid coordinates and world coordinates
- Description of variables in the binary data set

A detailed description of the components of a GrADS data descriptor file can be found in [GrADS]. Here is a list of the supported components: BYTESWAPPED, CHSUB, DSET, ENDVARS, FILEHEADER, HEADERBYTES, OPTIONS, TDEF, TITLE, TRAILERBYTES, UNDEF, VARS, XDEF, XYHEADER, YDEF, ZDEF

Note

Only 32-bit IEEE floats are supported for standard binary files!

Example

To convert a binary data file to NetCDF use:

```
cdo -f nc import_binary infile.ctl outfile.nc
```

Here is an example of a GrADS data descriptor file:

```
DSET ^ infile.bin
OPTIONS sequential
UNDEF −9e+33
XDEF 360 LINEAR −179.5 1
YDEF 180 LINEAR −89.5 1
ZDEF 1 LINEAR 1 1
TDEF 1 LINEAR 00:00 Z15jun1989 12hr
VARS 1
  param 1 99 description of the variable
ENDVARS
```

The binary data file infile.bin contains one parameter on a global 1 degree lon/lat grid written with FORTRAN record length headers (sequential).
2.14.2. IMPORTCMSAF - Import CM-SAF HDF5 files

Synopsis

import_cmsaf infile outfile

Description

This operator imports gridded CM-SAF (Satellite Application Facility on Climate Monitoring) HDF5 files. CM-SAF exploits data from polar-orbiting and geostationary satellites in order to provide climate monitoring products of the following parameters:

**Cloud parameters:** cloud fraction (CFC), cloud type (CTY), cloud phase (CPH), cloud top height, pressure and temperature (CTH, CTP, CTT), cloud optical thickness (COT), cloud water path (CWP).

**Surface radiation components:** Surface albedo (SAL); surface incoming (SIS) and net (SNS) shortwave radiation; surface downward (SDL) and outgoing (SOL) longwave radiation, surface net longwave radiation (SNL) and surface radiation budget (SRB).

**Top-of-atmosphere radiation components:** Incoming (TIS) and reflected (TRS) solar radiative flux at top-of-atmosphere. Emitted thermal radiative flux at top-of-atmosphere (TET).

**Water vapour:** Vertically integrated water vapour (HTW), layered vertically integrated water vapour and layer mean temperature and relative humidity for 5 layers (HLW), temperature and mixing ratio at 6 pressure levels.

Daily and monthly mean products can be ordered via the CM-SAF web page (www.cmsaf.eu). Products with higher spatial and temporal resolution, i.e. instantaneous swath-based products, are available on request (contact.cmsaf@dwd.de). All products are distributed free-of-charge. More information on the data is available on the CM-SAF homepage (www.cmsaf.eu).

Daily and monthly mean products are provided in equal-area projections. CDO reads the projection parameters from the metadata in the HDF5-headers in order to allow spatial operations like remapping. For spatial operations with instantaneous products on original satellite projection, additional files with arrays of latitudes and longitudes are needed. These can be obtained from CM-SAF together with the data.

Note

To use this operator, it is necessary to build CDO with HDF5 support (version 1.6 or higher). The PROJ library (version 5.0 or higher) is needed for full support of the remapping functionality.

Example

A typical sequence of commands with this operator could look like this:

```
cdo -f nc remapbil,r360x180 -import_cmsaf cmsaf_product.hdf output.nc
```

(bilinear remapping to a predefined global grid with 1 deg resolution and conversion to NetCDF).

If you work with CM-SAF data on original satellite project, an additional file with information on geolocation is required, to perform such spatial operations:

```
cdo -f nc remapbil,r720x360 -setgrid,cmsaf_latlon.h5 -import_cmsaf cmsaf.hdf out.nc
```

Some CM-SAF data are stored as scaled integer values. For some operations, it could be desirable (or necessary) to increase the accuracy of the converted products:
2.14.3. IMPORTAMSR - Import AMSR binary files

Synopsis

    import_amsr  infile  outfile

Description

This operator imports gridded binary AMSR (Advanced Microwave Scanning Radiometer) data. The binary data files are available from the AMSR ftp site (ftp://ftp.ssmi.com/amsre). Each file consists of twelve (daily) or five (averaged) 0.25 x 0.25 degree grid (1440,720) byte maps. For daily files, six daytime maps in the following order, Time (UTC), Sea Surface Temperature (SST), 10 meter Surface Wind Speed (WSPD), Atmospheric Water Vapor (VAPOR), Cloud Liquid Water (CLOUD), and Rain Rate (RAIN), are followed by six nighttime maps in the same order. Time-Averaged files contain just the geophysical layers in the same order [SST, WSPD, VAPOR, CLOUD, RAIN]. More information to the data is available on the AMSR homepage http://www.remss.com/amsr.

Example

To convert monthly binary AMSR files to NetCDF use:

    cdo -f nc amsre_yyyymm5  amsre_yyyymm5.nc
2.14.4. INPUT - Formatted input

Synopsis

\texttt{input,grid[,zaxis] outfile}
\texttt{inputsrv outfile}
\texttt{inputext outfile}

Description

This module reads time series of one 2D variable from standard input. All input fields need to have the same horizontal grid. The format of the input depends on the chosen operator.

Operators

\texttt{input} ASCII input
Reads fields with ASCII numbers from standard input and stores them in \texttt{outfile}. The numbers read are exactly that ones which are written out by the \texttt{output} operator.

\texttt{inputsrv} SERVICE ASCII input
Reads fields with ASCII numbers from standard input and stores them in \texttt{outfile}. Each field should have the header of 8 integers (SERVICE likely). The numbers that are read are exactly that ones which are written out by the \texttt{outputsrv} operator.

\texttt{inputext} EXTRA ASCII input
Read fields with ASCII numbers from standard input and stores them in \texttt{outfile}. Each field should have header of 4 integers (EXTRA likely). The numbers read are exactly that ones which are written out by the \texttt{outputext} operator.

Parameter

\begin{verbatim}
grid STRING Grid description file or name
zaxis STRING Z-axis description file
\end{verbatim}

Example

Assume an ASCII dataset contains a field on a global regular grid with 32 longitudes and 16 latitudes (512 elements). To create a GRIB1 dataset from the ASCII dataset use:

\begin{verbatim}
cdo -f grb input,r32x16 outfile.grb < my_ascii_data
\end{verbatim}
2.14.5. OUTPUT - Formatted output

Synopsis

output infiles
outputf, format[,nelem] infiles
outputint infiles
outputsrv infiles
outputext infiles

Description

This module prints all values of all input datasets to standard output. All input fields need to have
the same horizontal grid. All input files need to have the same structure with the same variables.
The format of the output depends on the chosen operator.

Operators

output ASCII output
Press prints all values to standard output. Each row has 6 elements with the C-style format
"%13.6g".

outputf Formatted output
Press prints all values to standard output. The format and number of elements for each row
have to be specified by the parameters format and nelem. The default for nelem is 1.

outputint Integer output
Prints all values rounded to the nearest integer to standard output.

outputsrv SERVICE ASCII output
Prints all values to standard output. Each field with a header of 8 integers (SERVICE
likely).

outputext EXTRA ASCII output
Prints all values to standard output. Each field with a header of 4 integers (EXTRA
likely).

Parameter

format STRING C-style format for one element (e.g. %13.6g)
nelem INTEGER Number of elements for each row (default: nelem = 1)

Example

To print all field elements of a dataset formatted with "%.4g" and 8 values per line use:

```
cdo outputf,%.4g,8 infile
```

Example result of a dataset with one field on 64 grid points:

```
<p>| | | | | | | | |</p>

```
2.14.6. OUTPUTTAB - Table output

Synopsis

\texttt{outputtab, params infiles outfile}

Description

This operator prints a table of all input datasets to standard output. \texttt{infiles} is an arbitrary number of input files. All input files need to have the same structure with the same variables on different timesteps. All input fields need to have the same horizontal grid.

The contents of the table depends on the chosen parameters. The format of each table parameter is keyname[:len]. len is the optional length of a table entry. Here is a list of all valid keynames:

<table>
<thead>
<tr>
<th>Keyname</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Parameter

\texttt{params} \hspace{1cm} \texttt{STRING} \hspace{1cm} Comma-separated list of keynames, one for each column of the table

Example

To print a table with name, date, lon, lat and value information use:

\texttt{cdo outputtab,name,date,lon,lat,value infile}

Here is an example output of a time series with the yearly mean temperature at lon=10/lat=53.5:

<table>
<thead>
<tr>
<th>#</th>
<th>name</th>
<th>date</th>
<th>lon</th>
<th>lat</th>
<th>value</th>
</tr>

</tbody>
</table>
2.14.7. OUTPUTGMT - GMT output

Synopsis

\[ \text{<operator>} \text{ infile} \]

Description

This module prints the first field of the input dataset to standard output. The output can be used to generate 2D Lon/Lat plots with [GMT]. The format of the output depends on the chosen operator.

Operators

**gmtxyz**  
GMT xyz format  
The operator exports the first field to the GMT xyz ASCII format. The output can be used to create contour plots with the GMT module pscontour.

**gmtcells**  
GMT multiple segment format  
The operator exports the first field to the GMT multiple segment ASCII format. The output can be used to create shaded gridfill plots with the GMT module psxy.

Example

1) GMT shaded contour plot of a global temperature field with a resolution of 4 degree. The contour interval is 3 with a rainbow color table.

```plaintext
   cdo gmtxyz temp > data.gmt  
   makecpt -T213/318/3 -Crainbow > gmt.cpt  
   pscontour -K -JQ0/10i -Rd -I -Cgmt.cpt data.gmt > gmtplot.ps  
   pscoast -O -J -R -Dc -W -B40g20 >> gmtplot.ps
```

2) GMT shaded gridfill plot of a global temperature field with a resolution of 4 degree. The contour interval is 3 with a rainbow color table.

```plaintext
   cdo gmtxyz temp > data.gmt  
   makecpt -T213/318/3 -Crainbow > gmt.cpt  
   pscontour -K -JQ0/10i -Rd -I -Cgmt.cpt data.gmt > gmtplot.ps  
   pscoast -O -J -R -Dc -W -B40g20 >> gmtplot.ps
```
cdo gmtcells temp > data.gmt
makecpt -T213/318/3 -Crainbow > gmt.cpt
psxy -K -JQ0/10i -Rd -L -Cgmt.cpt -m data.gmt > gmtplot.ps
pscoast -O -J -R -Dc -W -B40g20 >> gmtplot.ps
2.15. Miscellaneous

This section contains miscellaneous modules which do not fit to the other sections before.

### 2.15.1. GRADSDES - GrADS data descriptor file

**Synopsis**

```
gradsdes[,mapversion] infile
```

**Description**

Creates a [GrADS] data descriptor file. Supported file formats are GRIB1, NetCDF, SERVICE, EXTRA and IEG. For GRIB1 files the GrADS map file is also generated. For SERVICE and EXTRA files the grid have to be specified with the **CDO** option `\'-g <grid>``. This module takes `infile` in order to create filenames for the descriptor (`infile.ctl`) and the map (`infile.gmp`) file.

**Parameter**

`mapversion` INTEGER Format version of the GrADS map file for GRIB1 datasets. Use 1 for a machine specific version 1 GrADS map file, 2 for a machine independent version 2 GrADS map file and 4 to support GRIB files >2GB. A version 2 map file can be used only with GrADS version 1.8 or newer. A version 4 map file can be used only with GrADS version 2.0 or newer. The default is 4 for files >2GB, otherwise 2.

**Example**

To create a GrADS data descriptor file from a GRIB1 dataset use:

```
cdo gradsdes infile.grb
```

This will create a descriptor file with the name `infile.ctl` and the map file `infile.gmp`.

Assumed the input GRIB1 dataset has 3 variables over 12 timesteps on a Gaussian N16 grid. The contents of the resulting GrADS data description file is approximately:

```plaintext
DSET `infile.grb
DTYPE GRIB
INDEX `infile.gmp
XDEF 64 LINEAR 0.000000 5.625000

ENDVARS
```
2.15.2. AFTERBURNER - ECHAM standard post processor

Synopsis

after[,vct] infiles outfile

Description

The "afterburner" is the standard postprocessor for [ECHAM] GRIB and NetCDF data which provides the following operations:

- Extract specified variables and levels
- Compute derived variables
- Transform spectral data to Gaussian grid representation
- Vertical interpolation to pressure levels
- Compute temporal means

This operator reads selection parameters as namelist from stdin. Use the UNIX redirection "<namelistfile" to read the namelist from file.

The input files can’t be combined with other CDO operators because of an optimized reader for this operator.

Namelist

Namelist parameter and there defaults:

<table>
<thead>
<tr>
<th>TYPE</th>
<th>CODE</th>
<th>LEVEL</th>
<th>INTERVAL</th>
<th>MEAN</th>
<th>EXTRAPOLATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-1</td>
<td>-1</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

TYPE controls the transformation and vertical interpolation. Transforming spectral data to Gaussian grid representation and vertical interpolation to pressure levels are performed in a chain of steps. The TYPE parameter may be used to stop the chain at a certain step. Valid values are:

<table>
<thead>
<tr>
<th>TYPE</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Hybrid level spectral coefficients</td>
</tr>
<tr>
<td>10</td>
<td>Hybrid level fourier coefficients</td>
</tr>
<tr>
<td>11</td>
<td>Hybrid level zonal mean sections</td>
</tr>
<tr>

</tr>
<tr>
<td>60</td>
<td>Pressure level fourier coefficients</td>
</tr>
<tr>
<td>61</td>
<td>Pressure level zonal mean sections</td>
</tr>
<tr>
<td>70</td>
<td>Pressure level gauss grids</td>
</tr>
</tbody>
</table>

Vorticity, divergence, streamfunction and velocity potential need special treatment in the vertical transformation. They are not available as types 30, 40 and 41. If you select one of these combinations, type is automatically switched to the equivalent types 70, 60 and 61. The type of all other variables will be switched too, because the type is a global parameter.

CODE selects the variables by the ECHAM GRIB1 code number (1-255). The default value -1 processes all detected codes. Derived variables computed by the afterburner:
<table>

<td></td>
</tr>
</tbody>
</table>

**LEVEL** selects the hybrid or pressure levels. The allowed values depends on the parameter **TYPE**. The default value -1 processes all detected levels.

**INTERVAL** selects the processing interval. The default value 0 process data on monthly intervals. **INTERVAL=1** sets the interval to daily.

**MEAN=1** compute and write monthly or daily mean fields. The default value 0 writes out all timesteps.

**EXTRAPOLATE=0** switch of the extrapolation of missing values during the interpolation from model to pressure level (only available with **MEAN=0** and **TYPE=30**). The default value 1 extrapolate missing values.

Possible combinations of **TYPE**, **CODE** and **MEAN**:

<table>
<thead>
<tr>
<th>TYPE</th>

</tr>
<tr>
<td>&gt;11</td>
<td>all codes</td>
<td>0/1</td>
</tr>
</tbody>
</table>

**Parameter**

- **vct**  
  STRING  
  File with VCT in ASCII format

**Example**

To interpolate ECHAM hybrid model level data to pressure levels of 925, 850, 500 and 200 hPa, use:

```bash
  cdo after infile outfile << EON
    TYPE=30 LEVEL=92500,85000,50000,20000
  EON
```
2.15.3. FILTER - Time series filtering

Synopsis

bandpass,fmin,fmax  infile  outfile
lowpass,fmax  infile  outfile
highpass,fmin  infile  outfile

Description

This module takes the time series for each gridpoint in infile and (fast fourier) transforms it into the frequency domain. According to the particular operator and its parameters certain frequencies are filtered (set to zero) in the frequency domain and the spectrum is (inverse fast fourier) transformed back into the time domain. To determine the frequency the time-axis of infile is used. (Data should have a constant time increment since this assumption applies for transformation. However, the time increment has to be different from zero.) All frequencies given as parameter are interpreted per year. This is done by the assumption of a 365-day calendar. Consequently if you want to perform multiyear-filtering accurately you have to delete the 29th of February. If your infile has a 360 year calendar the frequency parameters fmin respectively fmax should be multiplied with a factor of 360/365 in order to obtain accurate results. For the set up of a frequency filter the frequency parameters have to be adjusted to a frequency in the data. Here fmin is rounded down and fmax is always rounded up. Consequently it is possible to use bandpass with fmin=fmax without getting a zero-field for outfile.

Hints for efficient usage:

• to get reliable results the time-series has to be detrended (cdo detrend)
• the lowest frequency greater zero that can be contained in infile is 1/(N*dT),
• the greatest frequency is 1/(2dT) (Nyquist frequency),

with N the number of timesteps and dT the time increment of infile in years.

Missing value support for operators in this module is not implemented, yet!

Operators

bandpass  Bandpass filtering
Bandpass filtering (pass for frequencies between fmin and fmax). Suppresses all variability outside the frequency range specified by [fmin,fmax].

lowpass  Lowpass filtering
Lowpass filtering (pass for frequencies lower than fmax). Suppresses all variability with frequencies greater than fmax.

highpass  Highpass filtering
Highpass filtering (pass for frequencies greater than fmin). Suppresses all variability with frequencies lower than fmin.

Parameter

fmin  FLOAT  Minimum frequency per year that passes the filter.
fmax  FLOAT  Maximum frequency per year that passes the filter.

Note

For better performance of these operators use the CDO configure option --with-fftw3.
Example
Now assume your data are still hourly for a time period of 5 years but with a 365/366-day- calendar and you want to suppress the variability on timescales greater or equal to one year (we suggest here to use a number x bigger than one (e.g. x=1.5) since there will be dominant frequencies around the peak (if there is one) as well due to the issue that the time series is not of infinite length). Therefore you can use the following:

```
cdo highpass,x -del29feb infile outfile
```

Accordingly you might use the following to suppress variability on timescales shorter than one year:

```
cdo lowpass,1 -del29feb infile outfile
```

Finally you might be interested in 2-year variability. If you want to suppress the seasonal cycle as well as say the longer cycles in climate system you might use

```
cdo bandpass,x,y -del29feb infile outfile
```

with x<=0.5 and y >=0.5.

2.15.4. GRIDCELL - Grid cell quantities

Synopsis

```
<operator> infile outfile
```

Description

This module reads the grid cell area of the first grid from the input stream. If the grid cell area is missing it will be computed from the grid coordinates. The area of a grid cell is calculated using spherical triangles from the coordinates of the center and the vertices. The base is a unit sphere which is scaled with the radius of the earth. The default earth radius is 6371000 meter. This value can be changed with the environment variable PLANET_RADIUS. Depending on the chosen operator the grid cell area or weights are written to the output stream.

Operators

- gridarea: Grid cell area
  Writes the grid cell area to the output stream. If the grid cell area have to be computed it is scaled with the earth radius to square meters.

- gridweights: Grid cell weights
  Writes the grid cell area weights to the output stream.

Environment

- PLANET_RADIUS: This variable is used to scale the computed grid cell areas to square meters. By default PLANET_RADIUS is set to an earth radius of 6371000 meter.
2.15.5. SMOOTH - Smooth grid points

Synopsis

smooth[,options] infile outfile
smooth9 infile outfile

Description

Smooth all grid points of a horizontal grid. Options is a comma-separated list of "key=value" pairs with optional parameters.

Operators

smooth Smooth grid points
Performs a N point smoothing on all input fields. The number of points used depend on the search radius (radius) and the maximum number of points (maxpoints). Per default all points within the search radius of 1degree are used. The weights for the points depend on the form of the curve and the distance. The implemented form of the curve is linear with constant default weights of 0.25 at distance 0 (weight0) and at the search radius (weightR).

smooth9 9 point smoothing
Performs a 9 point smoothing on all fields with a quadrilateral curvilinear grid. The result at each grid point is a weighted average of the grid point plus the 8 surrounding points. The center point receives a weight of 1.0, the points at each side and above and below receive a weight of 0.5, and corner points receive a weight of 0.3. All 9 points are multiplied by their weights and summed, then divided by the total weight to obtain the smoothed value. Any missing data points are not included in the sum; points beyond the grid boundary are considered to be missing. Thus the final result may be the result of an averaging with less than 9 points.

Parameter

nsMOOTH INTEGER Number of times to smooth, default nsMOOTH=1
radius STRING Search radius, default radius=1deg (units: deg, rad, km, m)
maxpoints INTEGER Maximum number of points, default maxpoints=<gridsize>
form STRING Form of the curve, default form=linear
weight0 FLOAT Weight at distance 0, default weight0=0.25
weightR FLOAT Weight at the search radius, default weightR=0.25

2.15.6. DELTAT - Difference between timesteps

Synopsis

deltat infile outfile

Description

This operator computes the difference between each timestep.
2.15.7. REPLACEVALUES - Replace variable values

Synopsis

\[
\text{setvals}, \text{oldval,newval[,...]} \quad \text{infile outfile} \\
\text{setrtoc}, \text{rmin,rmx},c \quad \text{infile outfile} \\
\text{setrtoc2}, \text{rmin,rmx},c,c2 \quad \text{infile outfile}
\]

Description

This module replaces old variable values with new values, depending on the operator.

Operators

- **setvals**  
  Set list of old values to new values
  Supply a list of n pairs of old and new values.

- **setrtoc**  
  Set range to constant
  \[ o(t,x) = \begin{cases} 
  c & \text{if } i(t,x) \geq rmin \land i(t,x) \leq rmax \\
  i(t,x) & \text{if } i(t,x) < rmin \lor i(t,x) > rmax 
  \end{cases} \]

- **setrtoc2**  
  Set range to constant others to constant2
  \[ o(t,x) = \begin{cases} 
  c & \text{if } i(t,x) \geq rmin \land i(t,x) \leq rmax \\
  c2 & \text{if } i(t,x) < rmin \lor i(t,x) > rmax 
  \end{cases} \]

Parameter

- **oldval,newval,**... FLOAT Pairs of old and new values
- **rmin** FLOAT Lower bound
- **rmx** FLOAT Upper bound
- **c** FLOAT New value - inside range
- **c2** FLOAT New value - outside range
2.15.8. VARGEN - Generate a field

Synopsis

\[ \text{const}, \text{const}.\text{grid} \quad \text{outfile} \]
\[ \text{random}, \text{grid},[\text{seed}] \quad \text{outfile} \]
\[ \text{topo},[\text{grid}] \quad \text{outfile} \]
\[ \text{seq}, \text{start}, \text{end},[\text{inc}] \quad \text{outfile} \]
\[ \text{stdatm}, \text{levels} \quad \text{outfile} \]

Description

Generates a dataset with one or more fields

Operators

**const**
Create a constant field
Creates a constant field. All field elements of the grid have the same value.

**random**
Create a field with random numbers
Creates a field with rectangularly distributed random numbers in the interval [0,1].

**topo**
Create a field with topography
Creates a field with topography data, per default on a global half degree grid.

**seq**
Create a time series
Creates a time series with field size 1 and field elements beginning with a start value in time step 1 which is increased from one time step to the next.

**stdatm**
Create values for pressure and temperature for hydrostatic atmosphere
Creates pressure and temperature values for the given list of vertical levels. The formulas are:

\[
P(z) = P_0 \exp \left( -\frac{g}{R} \frac{H}{T_0} \log \left( \frac{\exp \left( \frac{T_0 + \Delta T}{T_0 + \Delta T} \right)}{T_0 + \Delta T} \right) \right)
\]

\[
T(z) = T_0 + \Delta T \exp \left( -\frac{z}{H} \right)
\]

with the following constants

\[T_0 = 213\text{K} \quad \text{: offset to get a surface temperature of 288K}\]
\[\Delta T = 75\text{K} \quad \text{: Temperature lapse rate for 10Km}\]
\[P_0 = 1013.25\text{hPa} \quad \text{: surface pressure}\]
\[H = 10000.0\text{m} \quad \text{: scale height}\]
\[g = 9.80665 \frac{\text{m}}{\text{s}^2} \quad \text{: earth gravity}\]
\[R = 287.05 \frac{\text{J}}{\text{kgK}} \quad \text{: gas constant for air}\]

This is the solution for the hydrostatic equations and is only valid for the troposphere (constant positive lapse rate). The temperature increase in the stratosphere and other effects of the upper atmosphere are not taken into account.
Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</table>

Example

To create a standard atmosphere dataset on a given horizontal grid:

```
cdo enlarge,gridfile -stdatm,10000,8000,5000,3000,2000,1000,500,200,0 outfile
```

2.15.9. TIMSORT - Timsort

Synopsis

timsort  infile outfile

Description

Sorts the elements in ascending order over all timesteps for every field position. After sorting it is:

\[ o(t_1, x) \leq o(t_2, x) \quad \forall (t_1 < t_2), x \]

Example

To sort all field elements of a dataset over all timesteps use:

```
cdo timsort infile outfile
```
2.15.10. WINDTRANS - Wind Transformation

Synopsis

uvDestag, u,v[-/+0.5][-/+0.5] infile outfile
rotuvNorth, u,v infile outfile
projuvLatLon, u,v infile outfile

Description

This module contains special operators for datasets with wind components on a rotated lon/lat grid, e.g. data from the regional model HIRLAM or REMO.

Operators

uvDestag 
Destaggering of u/v wind components
This is a special operator for destaggering of wind components. If the file contains a grid with temperature (name='t' or code=11) then grid_temp will be used for destaggered wind.

rotuvNorth 
Rotate u/v wind to North pole.
This is an operator for transformation of wind-vectors from grid-relative to north-pole relative for the whole file. (FAST implementation with JACOBIANS)

projuvLatLon 
Cylindrical Equidistant projection
Thus is an operator for transformation of wind-vectors from the globe-spherical coordinate system into a flat Cylindrical Equidistant (lat-lon) projection. (FAST JACOBIAN implementation)

Parameter

u,v STRING 
Pair of u,v wind components (use variable names or code numbers)

-/+0.5,-/+0.5 STRING 
Destaggered grid offsets are optional (default -0.5,-0.5)

Example

Typical operator sequence on HIRLAM NWP model output (LAMH_D11 files):

cdo uvDestag,33,34 inputfile inputfile_destag

cdo rotuvNorth,33,34 inputfile_destag inputfile_rotuvN
2.15.11. ROTUVB - Rotation

Synopsis

```
rotuvb,u,v,... infile outfile
```

Description

This is a special operator for datasets with wind components on a rotated grid, e.g. data from the regional model REMO. It performs a backward transformation of velocity components U and V from a rotated spherical system to a geographical system.

Parameter

```
u,v,...  STRING     Pairs of zonal and meridional velocity components (use variable names or code numbers)
```

Note

This is a specific implementation for data from the REMO model, it may not work with data from other sources.

Example

To transform the u and v velocity of a dataset from a rotated spherical system to a geographical system use:

```
cdo rotuvb,u,v infile outfile
```

2.15.12. MROTUVB - Backward rotation of MPIOM data

Synopsis

```
mrotuvb infile1 infile2 outfile
```

Description

MPIOM data are on a rotated Arakawa C grid. The velocity components U and V are located on the edges of the cells and point in the direction of the grid lines and rows. With mrotuvb the velocity vector is rotated in latitudinal and longitudinal direction. Before the rotation, U and V are interpolated to the scalar points (cell center). U is located with the coordinates for U in infile1 and V in infile2. mrotuvb assumes a positive meridional flow for a flow from grid point(i,j) to grid point(i,j+1) and positive zonal flow for a flow from grid point(i+1,j) to point(i,j).

Note

This is a specific implementation for data from the MPIOM model, it may not work with data from other sources.
2.15.13. MASTRFU - Mass stream function

Synopsis

\texttt{mastrfu infile outfile}

Description

This is a special operator for the post processing of the atmospheric general circulation model [ECHAM]. It computes the mass stream function (code=272). The input dataset have to be a zonal mean of v-velocity [m/s] (code=132) on pressure levels.

Example

To compute the mass stream function from a zonal mean v-velocity dataset use:

\texttt{cdo mastrfu infile outfile}

2.15.14. DERIVEPAR - Derived model parameters

Synopsis

\texttt{<operator> infile outfile}

Description

This module contains operators that calculate derived model parameters. These are currently the parameters sea level pressure and geopotential height. All necessary input parameters are identified by their GRIB1 code number or the NetCDF CF standard name. Supported GRIB1 parameter tables are: WMO standard table number 2 and ECMWF local table number 128.

<table>
<thead>
<tr>
<th>CF standard name</th>
<th>Units</th>
<th>GRIB 1 code</th>
</tr>
</thead>
<tbody>
<tr>
<td>surface_air_pressure</td>
<td>Pa</td>
<td>134</td>
</tr>
<tr>
<td>air_temperature</td>
<td>K</td>
<td>130</td>
</tr>
<tr>
<td>specific_humidity</td>
<td>kg/kg</td>
<td>133</td>
</tr>
<tr>
<td>surface_geopotential</td>
<td>m² s⁻²</td>
<td>129</td>
</tr>
<tr>
<td>geopotential_height</td>
<td>m</td>
<td>156</td>
</tr>
</tbody>
</table>

Operators

\texttt{sealevelpressure}  
Sea level pressure
This operator computes the sea level pressure (\texttt{air pressure at sea level}). Required input fields are \texttt{surface\_air\_pressure}, \texttt{surface\_geopotential} and \texttt{air\_temperature} on full hybrid sigma pressure levels.

\texttt{gheight}  
Geopotential height
This operator computes the geopotential height (\texttt{geopotential\_height}) on full model levels in metres. Required input fields are \texttt{surface\_air\_pressure}, \texttt{surface\_geopotential}, \texttt{specific\_humidity} and \texttt{air\_temperature} on full hybrid sigma pressure levels. Note, this procedure is an approximation, which doesn’t take into account the effects of e.g. cloud ice and water, rain and snow.
2.15.15. ADISIT - Potential temperature to in-situ temperature and vice versa

Synopsis

\[ \text{<operator>}[\text{,pressure}] \text{ infile outfile} \]

Description

Operators

\textit{adisit} Potential temperature to in-situ temperature
This is a special operator for the post processing of the ocean and sea ice model [MPIOM].
It converts potential temperature adiabatically to in-situ temperature \( t_\theta, s, p \). Required input fields are sea water potential temperature \( \text{name=tho; code=2} \) and sea water salinity \( \text{name=sao; code=5} \). Pressure is calculated from the level information or can be specified by the optional parameter. Output fields are sea water temperature \( \text{name=to; code=20} \) and sea water salinity \( \text{name=s; code=5} \).

\textit{adipot} In-situ temperature to potential temperature
This is a special operator for the post processing of the ocean and sea ice model [MPIOM].
It converts in-situ temperature to potential temperature \( \text{tho}(t_\theta, s, p) \). Required input fields are sea water in-situ temperature \( \text{name=t; code=2} \) and sea water salinity \( \text{name=sao,s; code=5} \). Pressure is calculated from the level information or can be specified by the optional parameter. Output fields are sea water temperature \( \text{name=tho; code=2} \) and sea water salinity \( \text{name=s; code=5} \).

Parameter

\textit{pressure} FLOAT Pressure in bar (constant value assigned to all levels)

2.15.16. RHOPOT - Calculates potential density

Synopsis

\[ \text{rhopot}[\text{,pressure}] \text{ infile outfile} \]

Description

This is a special operator for the post processing of the ocean and sea ice model [MPIOM]. It calculates the sea water potential density \( \text{name=rhopot; code=18} \). Required input fields are sea water in-situ temperature \( \text{name=to; code=20} \) and sea water salinity \( \text{name=sao; code=5} \). Pressure is calculated from the level information or can be specified by the optional parameter.

Parameter

\textit{pressure} FLOAT Pressure in bar (constant value assigned to all levels)

Example

To compute the sea water potential density from the potential temperature use this operator in combination with \textit{adisit}:

\texttt{cdo rhopot \textasciitilde adisit infile outfile}
2.15.17. HISTOGRAM - Histogram

Synopsis

\(<\text{operator}>,\text{bounds} \ \text{infile} \ \text{outfile}\)

Description

This module creates bins for a histogram of the input data. The bins have to be adjacent and have non-overlapping intervals. The user has to define the bounds of the bins. The first value is the lower bound and the second value the upper bound of the first bin. The bounds of the second bin are defined by the second and third value, aso. Only 2-dimensional input fields are allowed. The output file contains one vertical level for each of the bins requested.

Operators

- **histcount**  
  Histogram count  
  Number of elements in the bin range.

- **histsum**  
  Histogram sum  
  Sum of elements in the bin range.

- **histmean**  
  Histogram mean  
  Mean of elements in the bin range.

- **histfreq**  
  Histogram frequency  
  Relative frequency of elements in the bin range.

Parameter

- **bounds**  
  FLOAT  
  Comma-separated list of the bin bounds (-inf and inf valid)

2.15.18. SETHALO - Set the left and right bounds of a field

Synopsis

\(\text{sethalo, lhalo, rhalo} \ \text{infile} \ \text{outfile}\)

Description

This operator sets the left and right bounds of the rectangularly understood fields. Positive numbers of the parameter \textit{lhalo} enlarges the left bound by the given number of columns from the right bound. The parameter \textit{rhalo} does the similar for the right bound. Negative numbers of the parameter \textit{lhalo}/\textit{rhalo} can be used to remove the given number of columns of the left and right bounds.

Parameter

- **lhalo**  
  INTEGER  
  Left halo

- **rhalo**  
  INTEGER  
  Right halo
2.15.19. WCT - Windchill temperature

Synopsis

\[ \text{wct} \ \text{infile1} \ \text{infile2} \ \text{outfile} \]

Description

Let \( \text{infile1} \) and \( \text{infile2} \) be time series of temperature and wind speed records, then a corresponding time series of resulting windchill temperatures is written to \( \text{outfile} \). The wind chill temperature calculation is only valid for a temperature of \( T < 33 \, ^\circ\text{C} \) and a wind speed of \( v > 1.39 \, \text{m/s} \). Whenever these conditions are not satisfied, a missing value is written to \( \text{outfile} \). Note that temperature and wind speed records have to be given in units of °C and m/s, respectively.

2.15.20. FDNS - Frost days where no snow index per time period

Synopsis

\[ \text{fdns} \ \text{infile1} \ \text{infile2} \ \text{outfile} \]

Description

Let \( \text{infile1} \) be a time series of the daily minimum temperature \( T_N \) and \( \text{infile2} \) be a corresponding series of daily surface snow amounts. Then the number of days where \( T_N < 0 \, ^\circ\text{C} \) and the surface snow amount is less than 1 cm is counted. The temperature \( T_N \) have to be given in units of Kelvin. The date information of a timestep in \( \text{outfile} \) is the date of the last contributing timestep in \( \text{infile} \).

2.15.21. STRWIN - Strong wind days index per time period

Synopsis

\[ \text{strwin}[v] \ \text{infile} \ \text{outfile} \]

Description

Let \( \text{infile} \) be a time series of the daily maximum horizontal wind speed \( V_X \), then the number of days where \( V_X > v \) is counted. The horizontal wind speed \( v \) is an optional parameter with default \( v = 10.5 \, \text{m/s} \). A further output variable is the maximum number of consecutive days with maximum wind speed greater than or equal to \( v \). Note that both \( V_X \) and \( v \) have to be given in units of m/s. Also note that the horizontal wind speed is defined as the square root of the sum of squares of the zonal and meridional wind speeds. The date information of a timestep in \( \text{outfile} \) is the date of the last contributing timestep in \( \text{infile} \).

Parameter

\[ \begin{align*}
\text{v} & \quad \text{FLOAT} & \text{Horizontal wind speed threshold (m/s, default v = 10.5 m/s)}
\end{align*} \]
2.15.22. STRBRE - Strong breeze days index per time period

Synopsis

strbre infile outfile

Description

Let infile be a time series of the daily maximum horizontal wind speed VX, then the number of days where VX is greater than or equal to 10.5 m/s is counted. A further output variable is the maximum number of consecutive days with maximum wind speed greater than or equal to 10.5 m/s. Note that VX is defined as the square root of the sum of squares of the zonal and meridional wind speeds and have to be given in units of m/s. The date information of a timestep in outfile is the date of the last contributing timestep in infile.

2.15.23. STRGAL - Strong gale days index per time period

Synopsis

strgal infile outfile

Description

Let infile be a time series of the daily maximum horizontal wind speed VX, then the number of days where VX is greater than or equal to 20.5 m/s is counted. A further output variable is the maximum number of consecutive days with maximum wind speed greater than or equal to 20.5 m/s. Note that VX is defined as the square root of the sum of squares of the zonal and meridional wind speeds and have to be given in units of m/s. The date information of a timestep in outfile is the date of the last contributing timestep in infile.

2.15.24. HURR - Hurricane days index per time period

Synopsis

hurr infile outfile

Description

Let infile be a time series of the daily maximum horizontal wind speed VX, then the number of days where VX is greater than or equal to 32.5 m/s is counted. A further output variable is the maximum number of consecutive days with maximum wind speed greater than or equal to 32.5 m/s. Note that VX is defined as the square root of the sum of squares of the zonal and meridional wind speeds and have to be given in units of m/s. The date information of a timestep in outfile is the date of the last contributing timestep in infile.
2.15.25. CMORLITE - CMOR lite

Synopsis

```
cmorlite,table[,convert] infile outfile
```

Description

The [CMOR] (Climate Model Output Rewriter) library comprises a set of functions, that can be used to produce CF-compliant NetCDF files that fulfill the requirements of many of the climate community’s standard model experiments. These experiments are collectively referred to as MIP’s. Much of the metadata written to the output files is defined in MIP-specific tables, typically made available from each MIP’s web site.

The CDO operator cmorlite process the header and variable section of such MIP tables and writes the result with the internal IO library [CDI]. In addition to the CMOR 2 and 3 table format, the CDO parameter table format is also supported. The following parameter table entries are available:

<table>
<thead>
<tr>
<th>Entry</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>WORD</td>
<td>Name of the variable</td>
</tr>
<tr>
<td>out_name</td>
<td>WORD</td>
<td>New name of the variable</td>
</tr>
<tr>
<td>type</td>
<td>WORD</td>
<td>Data type (real or double)</td>
</tr>
<tr>
<td>standard_name</td>
<td>WORD</td>
<td>As defined in the CF standard name table</td>
</tr>
<tr>
<td>long_name</td>
<td>STRING</td>
<td>Describing the variable</td>
</tr>
<tr>
<td>units</td>
<td>STRING</td>
<td>Specifying the units for the variable</td>
</tr>
<tr>
<td>comment</td>
<td>STRING</td>
<td>Information concerning the variable</td>
</tr>
<tr>
<td>cell_methods</td>
<td>STRING</td>
<td>Information concerning calculation of means or climatologies</td>
</tr>
<tr>
<td>cell_measures</td>
<td>STRING</td>
<td>Indicates the names of the variables containing cell areas and volumes</td>
</tr>
<tr>
<td>missing_value</td>
<td>FLOAT</td>
<td>Specifying how missing data will be identified</td>
</tr>
<tr>
<td>valid_min</td>
<td>FLOAT</td>
<td>Minimum valid value</td>
</tr>
<tr>
<td>valid_max</td>
<td>FLOAT</td>
<td>Maximum valid value</td>
</tr>
<tr>
<td>ok_min_mean_abs</td>
<td>FLOAT</td>
<td>Minimum absolute mean</td>
</tr>
<tr>
<td>ok_max_mean_abs</td>
<td>FLOAT</td>
<td>Maximum absolute mean</td>
</tr>
<tr>
<td>factor</td>
<td>FLOAT</td>
<td>Scale factor</td>
</tr>
<tr>
<td>delete</td>
<td>INTEGER</td>
<td>Set to 1 to delete variable</td>
</tr>
<tr>
<td>convert</td>
<td>INTEGER</td>
<td>Set to 1 to convert the unit if necessary</td>
</tr>
</tbody>
</table>

Most of the above entries are stored as variables attributes, some of them are handled differently. The variable name is used as a search key for the parameter table. valid_min, valid_max, ok_min_mean_abs and ok_max_mean_abs are used to check the range of the data.

Parameter

```
table STRING Name of the CMOR table as specified from PCMDI
convert STRING Converts the units if necessary
```

Example

Here is an example of a parameter table for one variable:

```
prompt> cat mypartab
&parameter
  name  = t
```
out_name = ta
standard_name = air_temperature
units = "K"
missing_value = 1.0e+20
valid_min = 157.1
valid_max = 336.3
/

To apply this parameter table to a dataset use:

cdo -f nc cmorlite,mypartab,convert infile outfile

This command renames the variable t to ta. The standard name of this variable is set to air_temperature and the unit is set to [K] (converts the unit if necessary). The missing value will be set to 1.0e+20. In addition it will be checked whether the values of the variable are in the range of 157.1 to 336.3. The result will be stored in NetCDF.

2.15.26. VERIFYGRID - Verify grid coordinates

Synopsis

    verifygrid  infile

Description

    This operator verifies the coordinates of all horizontal grids found in infile. Among other things, it searches for duplicate cells, non-convex cells, and whether the center is located outside the cell bounds. Use the CDO option -v to output the position of these cells. This information can be useful to avoid problems when interpolating the data.
3. Contributors

3.1. History

CDO was originally developed by Uwe Schulweida at the Max Planck Institute for Meteorology (MPI-M). The first public release is available since 2003. The MPI-M, together with the DKRZ, has a long history in the development of tools for processing climate data. CDO was inspired by some of these tools, such as the PINGO package and the GRIB-Modules.

PINGO\(^1\) was developed by Jürgen Waszkewitz, Peter Lenzen, and Nathan Gillet in 1995 at the DKRZ, Hamburg (Germany). CDO has a similar user interface and uses some of the PINGO routines.

The GRIB-Modules was developed by Heiko Borgert and Wolfgang Welke in 1991 at the MPI-M. CDO is using a similar module structure and also some of the routines.

3.2. External sources

CDO has incorporated code from several sources:

afterburner is a postprocessing application for ECHAM data and ECMWF analysis data, originally developed by Edilbert Kirk, Michael Ponater and Arno Hellbach. The afterburner code was modified for the CDO operators after, ml2pl, ml2hl, sp2gp, gp2sp.

SCRIP is a software package used to generate interpolation weights for remapping fields from one grid to another in spherical geometry [SCRIP]. It was developed at the Los Alamos National Laboratory by Philip W. Jones. The SCRIP library was converted from Fortran to ANSI C and is used as the base for the remapping operators in CDO.

YAC (Yet Another Coupler) was jointly developed by DKRZ and MPI-M by Moritz Hanke and Rene Redler [YAC]. CDO is using the clipping and cell search routines for the conservative remapping with remapcon.

libkdtree a C99 implementation of the kd-tree algorithm developed by Jörg Dietrich.

CDO uses tools from the GNU project, including automake, and libtool.

3.3. Contributors

The primary contributors to the CDO development have been:

Uwe Schulweida : Concept, design and implementation of CDO, project coordination, and releases.

Luis Kornblueh : He supports CDO from the beginning. His main contributions are GRIB performance and compression, GME and unstructured grid support. Luis also helps with design and planning.

Ralf Müller : He is working on CDO since 2009. His main contributions are the implementation of the User Portal, the ruby and python interface for all CDO operators, the building process and the Windows support. The CDO User Portal was funded by the European Commission infrastructure project IS-ENES. Ralf also helps a lot with the user support. Implemented operators: intlevel3d, consecsum, consects, ngrids, ngridpoints, reducegrid

\(^{1}\)Procedural INterface for GRIB formatted Objects
Cedrick Ansorge: He worked on the software package CDO as a student assistant at MPI-M from 2007-2011. Implemented operators: eof, eof3d, enscrps, ensbrs, maskregion, bandpass, lowpass, highpass, smooth9

Oliver Heidmann: He worked on the software package CDO as a student assistant at MPI-M from 2015-2018.

Karin Meier-Fleischer: She is working in the CDO user support since 2017.

Fabian Wachsmann: He is working on CDO for the CMIP6 project since 2016. His main task is the implementation and support of the cmor operator. He has also implemented the ETCCDI Indices of Daily Temperature and Precipitation Extremes.

Ralf Quast: He worked on CDO on behalf of the Service Gruppe Anpassung (SGA), DKRZ in 2006. He implemented all ECA Indices of Daily Temperature and Precipitation Extremes, all percentile operators, module YDRUNSTAT and wct.

Kameswarrao Modali: He worked on CDO from 2012-2013. Implemented operators: contour, shaded, grfill, vector, graph.

Michal Koutek: Implemented operators: selmulti delmulti, changemulti, samplegrid, uvDestag, rotnorth, projuvLatLon.

Etienne Tourigny: Implemented operators: setclonlatbox, setcindexbox, setvals, splitsel, histfreq, setrtoc, setrtoc2.

Asela Rajapakse: He worked on CDO from 2016-2017 as part of the EUDAT project. Implemented operator: verifygrid

Estanislao Gavilan: Improved the CDO documentation for the installation section.

Many users have contributed to CDO by sending bug reports, patches and suggestions over time. Very helpful is also the active participation in the user forum of some users. Here is an incomplete list:

A. Environment Variables

The following table describes the environment variables that affect CDO.

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDO_DOWNLOAD_PATH</td>
<td>None</td>
<td>Path where CDO can store downloads.</td>
</tr>
<tr>
<td>CDO_FILE_SUFFIX</td>
<td>None</td>
<td>Default filename suffix. This suffix will be added to the output file name instead of the filename extension derived from the file format. NULL will disable the adding of a file suffix.</td>
</tr>
<tr>
<td>CDO_GRIDSEARCH_RADIUS</td>
<td>180</td>
<td>Grid search radius in degree. Used by the operators setmisstonn, remapdis and remapnn.</td>
</tr>
<tr>
<td>CDO_HISTORY_INFO</td>
<td>true</td>
<td>'false' don’t write information to the global history attribute.</td>
</tr>
<tr>
<td>CDO_ICON_GRIDS</td>
<td>None</td>
<td>Root directory of the installed ICON grids (e.g. /pool/data/ICON).</td>
</tr>
<tr>
<td>CDO_PCTL_NBINS</td>
<td>101</td>
<td>Number of histogram bins.</td>
</tr>
<tr>
<td>CDO_RESET_HISTORY</td>
<td>false</td>
<td>'true' resets the global history attribute.</td>
</tr>
<tr>
<td>CDO_REMAP_NORM</td>
<td>fracarea</td>
<td>Choose the normalization for the conservative interpolation</td>
</tr>
<tr>
<td>CDO_TIMESTAT_DATE</td>
<td>None</td>
<td>Set target timestamp of a temporal statistic operator to the 'first', 'middle', 'midhigh' or 'last' contributing source timestep.</td>
</tr>
<tr>
<td>CDO_USE_FFTW</td>
<td>1</td>
<td>Set to 0 to switch off usage of FFTW. Used in the Filter module.</td>
</tr>
<tr>
<td>CDO_VERSION_INFO</td>
<td>true</td>
<td>'false' disables the global NetCDF attribute CDO.</td>
</tr>
</tbody>
</table>
B. Parallelized operators

Some of the CDO operators are parallelized with OpenMP. To use CDO with multiple OpenMP threads, you have to set the number of threads with the option `-P`. Here is an example to distribute the bilinear interpolation on 8 OpenMP threads:

```
cdo -P 8 remapbil,targetgrid infile outfile
```

The following CDO operators are parallelized with OpenMP:

<table>
<thead>
<tr>

D. Grid description examples

D.1. Example of a curvilinear grid description

Here is an example for the CDO description of a curvilinear grid. xvals/yvals describe the positions of the 6x5 quadrilateral grid cells. The first 4 values of xbounds/ybounds are the corners of the first grid cell.

```
gridtype = curvilinear
gridsize = 30
xsize = 6
ysize = 5
xvals = -21 -11 0 11 21 30 -25 -13 0 13
      25 36 -31 -16 0 16 31 43 -38 -21
      0 21 38 52 -51 -30 0 30 51 64
xbounds = -23 -14 -17 -28 -14 -5 -6 -17 -5 5 6 -6
        5 14 17 6 14 23 28 17 23 32 38 28
       -28 -17 -21 -34 -17 -6 -7 -21 -6 6 7 -7
       6 17 21 7 17 28 34 21 28 38 44 34
      -34 -21 -27 -41 -21 -7 -9 -27 -7 7 9 -9
      7 21 27 9 21 34 41 27 34 44 52 41
      9 27 35 13 27 41 51 35 41 52 63 51
   13 35 51 21 35 51 67 51 51 63 77 67
yvals = 29 32 32 32 29 26 39 42 42 42
      39 35 48 51 52 51 48 43 57 61
     62 61 57 51 65 70 72 70 65 58
ybounds = 23 26 36 32 26 27 37 36 27 27 37 37
        27 26 36 37 26 23 32 36 23 19 28 32
        32 36 45 41 36 37 47 45 37 37 47 47
        37 36 45 47 36 32 41 45 32 28 36 41
       41 45 55 50 45 47 57 55 47 47 57 57
      47 45 55 57 45 41 50 55 41 36 44 50
      50 55 64 58 55 57 67 64 57 57 67 67
      57 55 64 67 55 50 58 64 50 44 51 58
     58 64 72 64 64 67 77 72 67 67 77 77
    67 64 72 77 64 58 64 72 58 51 56 64
```

Figure D.1.: Orthographic and Robinson projection of the curvilinear grid, the first grid cell is colored red
D.2. Example description for an unstructured grid

Here is an example of the CDO description for an unstructured grid. xvals/yvals describe the positions of 30 independent hexagonal grid cells. The first 6 values of xbounds/ybounds are the corners of the first grid cell. The grid cell corners have to rotate counterclockwise. The first grid cell is colored red.

<table>
